LEVIS, R. J., Clinic, 136.
LILLIBRIDGE, B. J., 251.
LITTLE, W. S., 228.

McSWEENY, DAN'L E., 573.
MERCUR, W. H., Report, 617.
MICHENER, E., 218.
MILLS, C. K., Lecture, 104, 168, 232, 554.
MINER, J. L., 708.
MORRISON, W. H., Report, 72, 168, 200, 232, 391 424, 456. 554, 651, 775.
MUSSER, J. H., 550, 577, 613, 646.

NANCREDE, C. B., Clinic, 33, 65, 545.
NEFF, JOSEPH, Clinic, 106.
NEWTON, C. B., 421.

O'BRIEN, M. W., 700.
OPPELT, E. A., 542, 700.

PARRISH, W. H., Clinic, 105.
PARSON, J. W. 446.
PEPPER, W., Clinic, 391, 775.
PORTER, P. B., Report, 715.

RAMSEY, GEO. M., 541.
REDMAN, SPENCE, 93.
REYNOLDS, DUDLEY S., 27, 58.
RILEY, H. K., 488.
ROBERTS, J. B., 36.
ROY, G. C., 100.

SCHAEFER, THEO., 168.
SCHMIDT, C. H., 379.
SCHULTZ, S. S., 727.
SÉE, GERMAIN, PROF., 678, 712.
SEELYE, W. H., Report, 266, 298, 489, 681.
SHOEMAKER, J. V., 161, 732.
SILVERTHORN, L. L., 445.
SLAY, J. CLARK, 379.
SMITH, T. CURTIS, 385.
SOZINSKEY, THOS. S., 417.
STANLEY, THEO., Report, 584.
STEINBACH. L. W., 39.
STILLMAN, W. O., 413.

TAYLOR, T. L., 669.
THOMAS, T. G., Clinic, 193, 225, 289, 321, 715.
THORNTON, CHARLES C., 123.
THROCKMORTON, TOM M., 357.
TURNBULL, L., Report, 472, 505, 609, 649.
TURNBULL, C. S., 697, 728.
TYSON, JAMES, Clinic, 72.
TYSON, J. L., 475.

VAN HARLINGEN, A., 731.

WARD. S. M., 453.
WATHEN, W. H., Clinic, 329, 360.
WAUGH, W. F., 328.
WEBB, W. H., 513, 546.
WHARTON, H. R., 735.
WHITE, J. WILLIAM, 773, 797.
WOOD, H. C., Clinic, 108, 456.

INDEX.

Abdomen, contusion of, 6; sponge in, 347.
Abdominal section, 310; cases of, 121, 135; disorders, applications of electricity in, 523.
Abnormal positions of head, 129.
Abortive treatment of diphtheria, 539.
Abortions, injections of carbolic acid in, 188.
Abortions, repeated, treated with, 367.
Abscess, acute pelvic, 219; psoas, treatment of, 292; large pelvic, 407.
Abscess in supra-renal capsules, 619.
Absorbent cotton, an electrode covering, 403.
Acid, phenic in, 89; carbolic in, 188; in indigestion, 537; in gastric disorders, 761; nitric, in intra-uterine applications of, 120; osmic, in sciatica, 186.
Acne rosacea, treatment of, 274.
Aconite in frostbite, 251.
Acute, gouty dementia, 141; purpura hemorrhagica in child, 150; laryngitis, treatment of, 186; pelvic abscess, 219; erysipelas, pilocarpine in, 241; dysentery, treatment of, 313, 345; rheumatism, oil of wintergreen in, 370; endocarditis in, 656; and chronic endocarditis, 746; earache, glycerinum acidi carbolici in, 781.
Adeno-fibroma of lachrymal gland, 272.
Adenoid vegetations of pharynx, treatment of, 538.
Administration, of alcohol to parturient women, 47; of nitrous oxide, 119.
Adolescents, cardiac hypertrophy in, 568, 746.
Adulteration of medicines, the increasing, 309.
Adults, poliomyelitis, anterior, 503.
Aged persons, operations on, 58; hygiene of, 108, 347.
Agoraphobia, 113.
Ague, splenic murmur in, 760.
Albumen in urine, determination of, 632.
Albuminuria, after chloroform, 186; production of, 333; regularly intermittent, 402.
Alcohol, to parturient women, 47; in disease, 445.
Alcoholic liquors, abuse of, 191.
Alexander operation, 751.
Alimentation, rectal, 282.
Alimentary canal, 470.
Altitudes, high, pneumonia in, 399.
Aluminus glycerinum, 377.
Alveolar sarcoma of kidney, 271.
Alveloz for cancer, 444.
Amenorrhœa, 669; and gonorrhœa, 347.
Ammonia, in treatment of septicæmia, 441; in scarlet fever, carbonate of, 471, 634.
Amyloid degeneration of liver, spleen, kidneys, 776.
An ideal medical life, 446.
Anæmia, idiopathic, 550, 577, 613, 646.
Anæsthesia, rectal, 217.
Anæsthetic, rhigolene as, 179; rapid, by ether, 530; local, 632; in labor, bromide of ethyl an, 683; local, methyl chloride as, 759.
Anæsthetics, precautions in administration of, 23; in midwifery, 359.
Anal fistule, 139.
Analysis, a novel urinary, 126; of idiopathic anæmia, 550, 577, 613, 646.
Anatomical geometry and toponymy, 219.
Anatomy, comparative, 446.
Anchylosis, case of, 779.
Anecdote of Garfield, 319.
Aneurism, cardiac, 429, 459; ilio-femoral, 563; of splenic artery, 596; of aorta, with rupture, 620; double of, 654.
Anginose diphtheria, specimens from, 460.
Ani, sphincter, dilatation of, 328.
Animal, man as a cooking, 278.
Anomalous post epileptic state, 689.
Anteflexion of uterus, 195.
Anthrax, treatment of, 157.
Antipyrin. Huchard on, 117.
Anti-vaccinator's funeral, 125.
Antimonial wine in diseases of skin, 596.
Antipyretic, another, Thallin, 26; surgery, 353, 449.
Antiseptic, obstetrical, perchloride of mercury as, 152.
Antrum, chronic suppuration in, 783.
Anus, foreign body in, 357, 388.
Aphasia, traumatic, 238, 379.
Apoplexy, probable, 458.
Apormorphine, hydrochlorate of, 92.
Applications of nitric acid, 120; of cocaine to urethra, 183.
Arsenic in cancer, 630.
Arsenical paralysis, 376.
Arcus senilis in boy, 568.
Artery, splenic aneurism of, 596.
Arthritis, suppurative, 33.
Arthropathia progressiva, 434.
Arthropathies, the spinal, 302, 331.
Artificial impregnation, 31; feeding, 221; teeth, swallowing, 638.
Artificial teeth, swallowing of, 788.
Aseptic silk, 412.
Asiatic cholera, 257.
Aspiration of strangulated hernia, 89.
Asthma, thyroid, case of, 154; caused by, 539.
Astigmatism and sick headache, relations of, 153.
Astragalus, excision of, 272.
Ataxia, locomotor, 276, 332; fracture of, 664.
Athletes, young women as, 319.
Athetosis, bilateral, 466.
Atmosphere of phthisical patients, 679.

Atom and molecule, 782.
Atropia in severe electric shock, 409.
Atrophy, muscular, tabes and progressive, 281.
Auricle, right wound of vena cava and, 538.
Auto-infection, puerperal fever due to, 198.
Auxiliary method for reduction of dislocations, 97.
Avoidable illness, 637.

Baby, a Japanese, 318; washing the, 572.
Bacilli, specific, in syphilitic tissues, 629.
Bacillus, the comma, 16; of infantile diarrhœa, 154; comma, Koch on, 145.
Bacteriology run wild, 504.
Bandaging, 491; and rest, treatment of mastitis by, 342.
Baths, Russian, 82.
Beer in vomiting of pregnancy, 634.
Belladonna in incontinence, large doses of, 443.
Bichloride of mercury in diphtheria, 377.
Bilateral, herpes zoster, 206; athetosis, 466.
Births, still, statistics of, 417.
Bladder, washing out, 155; inverted, 156; foreign body in, 187; laceration of, 357, 388; urinary of, hypospadias, 402; irritable, cocaine in, 411; simulating stone, needle in, 497; excessive irritability of, 715.
Bleeding, drunkenness treated by, 346.
Blindness, night, 18; color and railway accidents, 147.
Blood-letting, history of, 111.
Bones of upper extremity, multiple fracture of, 185.
Bony union possible, 234.
Boy, arcus senilis in, 568.
Bowels in infants, treatment of ulceration of, 755.
Bradford county medical society, 808.
Brain, removal of tumor from, 25; phantom, 44; excision of tumor from, 186; lodgment of breech-pin in, 444; a composite organ, 465; idiot skull and, 588; affection complicating pneumonia, 693.
Bright's disease, caffeine in, 410.
Bromide of potassium in, 154; of ethyl, an anæsthetic in labor, 683.
Bronchitis, simple diagnostic differences, 651.
Brutality, a sad instance of, 350.
Bullet wound of lung, 340.
Buttermilk in sick stomach, 623.

Cæsarian section, 412.
Caffeine in Bright's diseases, 410; a cardiac stimulant, 442.
Calcium, sulphide of, 311.
Calculi in female, 301.
Calculus pyelitis, case of, 655.
Camphor phenol, 168; essential oil in rheumatism, 633.
Cancer of peritoneum, 249; of thyroid body, 409; alveloz for, 444; smoking a cause of, 538; œsophageal treatment of, 569; cocaine in, 570; arsenic in, 630.
Cannabis indica in, 184.
Cannibalism, 126.
Capital punishment, 85.
Carbolic acid in abortion, injections of, 188; in indigestion, 537.
Carbonate of ammonia in scarlet fever, 471, 634; in gastric disorders, 761.
Carbuncle, disinfectants on, 146; without incision, treatment of, 756.
Carcinoma, of stomach in child, 17; resection of pylorus for, 93.
Carcinosis, general, 53.
Cardiac debility, 119; aneurism, 429, 459; stimulant, caffeine as, 442; hypertrophy in adolescents, 568; disease in adolescence, 746.
Caries of cricoid cartilage, 24; excision of astragalus for, 272.
Case of thyroid asthma, 154; of monstrosity, 536.
Caseous pneumonia of entire lung, 112.
Castor beans, poisoning with, 625.
Castration for hystero-epilepsy, 230; by a hog, 700.
Cataract, incipient diagnosis of, 729.
Cataractous lens, in capsule, removal of, 219.
Catarrh, etiology of, 209; cervical, and retroversion, 227.
Catarrhal rhinitis, saliva officinalis in, 377; inflammation of ear, 634.
Cattle, pleuro-pneumonia of, 13.
Cerebro-spinal meningitis, review of, 634.
Centenarian, 218.
Cephalagia, syphilitic, 681.
Cerebellum, tumor of, 586; tubercular, 790.
Cerebral pneumonia, 107; syphilis, 215; studies, 320; pathology, 435; softening, 530; lesion, temperature in diabetes mellitus, due to, 571.
Cervical catarrh and, 227; pregnancy, 299.
Cervix uteri, laceration of, 195.
Charcot's joints, 302; locomotor ataxia with, 332.
Cheese poisoning, 31.
Chemical analysis of food, 350.
Cherry pit in ear of child, 208.
Cigar-smoking and cancer, 479.
Child, carcinoma of stomach in, 17; bed, graver fevers of, 18; acute purpura hemorrhagica in, 150.
Children, new-born, causes of death in, 93; psychical troubles among, 241; urine of, 282; chloral in convulsions of, 409; of idiots, 414; incontinence of urine in, 432; nerve system of, 668.
Childhood, febrile attacks in, 184.
Chin reflex, 591.
Chinese diagnosis of leprosy, 795.
Chloral hydrate, poisoning from, 237; for chordee, 378; in convulsions of children, 409.
Chloroform, albuminuria after, 186; inhalations, chorea treated by, 186; habit, 350, 632.
Chloride, methyl, a local anæsthetic, 759.
Cholera, 303; diarrhœa treatment of, 22; its travels, 147; Asiatic, 257; treatment of, 148; contagion of, 214; epidemic in Paris, 243; new view, 317; bacillus, Dr. Klein on, 351; and marriage, 381; sanitary precautions against, 535; tannic acid injections in, 567; intravenous injections in, 571; precautions, 638; inoculation for, 694.
Chordee, cocaine in, 345; chloral hydrate for, 378.
Chorea, 376; in aged, 25; investigation of, 158; treated with chloroform inhalations, 186; hereditary, 697.
Chronic dysentery, voluminous enemata in, 81; interstitial nephritis, 796; suppuration in antrum, 783.
Contracted kidney, 141; parenchymatous nephritis, 273; ulcer of leg, 622.
Circumcision under peculiar circumstances, 573.

Cirrhosis of liver, convulsions from, 651.
City *vs.* country, 787.
Cleanliness in labor cases, 412.
Cleansing of wounds, 462.
Clavicle; dislocation of, 215; sarcoma of, 270.
Climate and intellect, 413.
Clinical thermometry, 182.
Coca, valoid of, 315; in fatigue, 561.
Cocaine, muriate of, 27, 58; preparation of, 49; in dysphagia, 56; in neuralgia, 57; hydrochlorate of, 79, 89; in sleeplessness, 90; in laryngology, 122; and coca, physiological action of, 176; German views on, 178; to urethra, application of, 183; in dysmenorrhœa, 178; hydrochlorate of, 220; therapeutic action of, 228; in removal of foreign bodies from eye, 284; in minor surgery, 313, 344; in rectal surgery, 314; muriate of, 315; in vaginismus, 315; in chordee, 345; muriate in gout, 347; observations on action of, 370; in chronic cystitis, 411; in operation for phimosis, 539; in urethral spasm, 540; in cancer, 570; hydrochlorate in, 634; in vomiting of pregnancy, 659; in senile gangrene, 723.
Cod-liver oil in scalded throat, 759.
Coccyx, removal of, 503.
Colchicin, supposed poisoning by, 375; poisoning by, 571.
Collapse, electricity in, 569.
Colleges, hygiene of, 574.
Comfort for invalids traveling, 63.
Comma bacillus, 16; Kussmaul, S., 90; uræmic, 106.
Communicability of consumption, 724; of scarlet fever, 789.
Comparative anatomy, 446.
Complicated multiple sclerosis, 788.
Compression, instrumental, 563.
Composite organ, the brain, 465.
Compulsory vaccination, 87.
Concussion of spine, 210.
Condensed milk, value of, 114.
Condyloma, urethræ, 720.
Conferences, sanitary, 534.
Congenital, deficiency of, 617.
Conjunctivitis, diphtheritic, 228.
Constipation, ergot in, 540.
Constitutional syphilis, 185.
Consumption, pulmonary, hereditary transmission of, 311; communicability of, 724.
Contagion of cholera, 214.
Contagiousness of typhoid fever, 55; of tuberculosis, 513, 546.
Contracture, muscular, cure of, 153.
Contusion of abdomen, case of, 6.
Convulsions, 266, 299; of children, chloral in, 409; from cirrhosis of liver, 651.
Cornea, diseases of, 520.
Cough, grindelia robusta in, 346.
Craniotomies in same subject, 187; successive in same subject, 700.
Cremation in France, 415.
Cricoid cartilage, caries of, 24.
Crime, dentistry to detection of, 158,
Criminals, experiments on heads of, 807.
Croup, membranous, 564.
Crow and country doctor, 414.
Culture, physical, 542.
Cupping, dry, in treatment of anthrax, 157.
Cure of muscular contracture, 153; snow, 177.
Custom breeds tolerance, 412.
Cyst, parovarian, removal of, 11; papillomatous ovarian, 559; ovarian, 683.
Cystitis, chronic, cocaine in, 411.
Cystomata, ovarian, 748.
Cysts of utero-vaginal glands, 291; ovarian, 300; papillary ovarian, 749.

Dead, apparently, revival of, 217; bodies, discoloration of, 566.
Deafness, sudden mumps a cause of, 156; hereditary? 348.
Death, causes of, in new-born children, 93; from sudden pulmonic œdema, 141; apparent, 351; rare case of sudden, 504; from cold douche, 532; from hurry and exertion, 543; debauchee's fear of, 636.
Debauchee's fear of death, 636.
Decrease of population in France, 414.
Deformities, general treatment of, 545; osteotomy for correction of, 735.
Degeneration among residents of large cities, 341; amyloid, of liver, spleen, kidneys, 776.
Delusions, 232.
Dementia, acute gouty, 141.
Dentistry to detection of crime, 158.
Depopulation of France, syphilis and, 537.
Dermatitis medicamentosa, 731.
Desquamative, inflammation of, 609, 649.
Detection of poison in sausages, 149.
Diabetes; mellitus, skim-milk in, 26; bromide of potassium in, 154; temperature in, 571.
Diagnosis; usefulness of nose in, 50; of gastric disease, 58; new method of, 155; refinements of, 244; of incipient cataract, 729; of carcinoma, 806.
Diagnostic; errors and practical hints, 281; sign, varicosity of lingual vein as, 689; differences between simple bronchitis and, 651.
Diarrhœa; cholera, treatment of, 22; infantile, 91; vinegar in, 314; Monsel's iron in, 371.
Died from whipping, 191.
Digestion, disorders of, 687.
Dilatation of sphincter ani in, 328.
Dinner, advantages of, 318.
Diphtheria; bichloride of mercury in, 377; angina nose, case of, 460; abortive treatment of, 539; laryngeal, 557; treatment of, 699.
Diphtheritic; conjunctivitis, 228; croup, 564.
Diplomas, American, in Europe, sale of, 212.
Disease; of uterus, 11; gastric, diagnosis of, 58; excision for hip-joint, 65; inebriety, 100; investigation of, 115; malignant, of kidney, 273; Bright's, caffeine in, 410; germinal, view of, 414; alcohol in, 445.
Diseases; of throat and nose, cocaine in, 89; of women, 225, 289, 321, 715; of rectum, 328; of cornea, 520; of skin, antimonial wine in, 596; among Indians, 703; of skin of reflex, nervous causation, 740.
Disinfectants, 444; on carbuncle, 146.
Disinfection, 54.
Dislocation; at knee, 93; auxiliary method for reduction of, 97; of clavicle, 215; sub-spinous of humerus, 411.
Disorders of early childhood, 164, 196.
Dispensary experience, suggestions from, 461.
Disturbances of normal vaso-motor tonus, 172, 205.
Diuretic mixture, 346.

Doctor, royal, 62; Holmes, an estimate of, 189; wife, 639.
Dorsal vertebræ, spondylitis of, 619.
Dorsalis, spasmodic tabes, 364, 525.
Double uterus and vagina, 362.
Douche, cold, death from, 532.
Drainage, post-partum, of uterus, 564.
Dressing of wounds, 462.
Drunkards, juvenile, 621.
Drunkenness treated by bleeding, 346.
Dryness of tongue, glycerine for, 345.
Dry cupping in treatment of anthrax, 157.
Dupuytren's contraction, hereditary transmission of, 539.
Duties of cities in epidemics, 373.
Dysentery; chronic, nitrate of silver in, 81; vinegar in, 314; ipecacuanha, 470; acute treatment of, 313, 345.
Dysmenorrhœa, cocaine in, 178.
Dysphagia; cocaine in, 56; urticaria and, 504.

Ear of child, cherry-pit in, 209.
Earache, acute, treatment of, 781.

THE EXAMINATION OF PATIENTS.

A Clinical Lecture Delivered at the Medico-Chirurgical College of Philadelphia,

BY PROF. H. ENGEL, M. D.

As there is, accidentally, no new case on hand that would permit me practically to demonstrate some of those nervous diseases, of which I have thus far given you a theoretical description in my didactic lectures, I shall endeavor to train you in the examination of patients. As consulting physician, I have often had the opportunity to make the following observation: A young doctor is called to attend a patient, but notwithstanding his best efforts, he does not succeed in recognizing the nature of the malady, from which the sick individual is suffering. He ultimately asks, perhaps, his former preceptor to see the case with him, and, to his surprise, while his teacher is questioning the patient, everything appears clear to him, the veil seems to be lifted from his eyes, and he correctly diagnosticates the disease, before the consultant has concluded the investigation and pronounced his opinion. Again, let two physicians, equally expert, together consult at the bedside of a sufferer, and let the one be the attending, the other the consulting physician, the nature of the case being so complicated as to make an exchange of opinion desirable. Certainly the attending doctor, who has, probably, visited the patient several times previously, may be supposed to know more about the case than his colleague, who sees the sick individual for the first time. The consultant commences his examination; from a few questions, the attending physician at once recognizes that his confrère is on a wrong scent, and to save him unnecessary labor, by a remark or two he guides his colleague's view of the case into a totally different channel, which, as one single question may announce to the attending doctor, again is a mistaken one, and which is once more corrected in a similar manner, until, finally, the examination reaches the point where the superior skill of the one or the other will decide the doubtful diagnosis.

In the first case cited, the young physician recognizes in the series of questions which his teacher puts to the patient a familiar picture of a disease known to him, while in the second case the attending physician had previously followed the same wrong paths, that he observes his colleague to take. To enable you to examine a patient in such a manner, as at once to permit the listener, if an expert, to guess the disease whose existence you wish to establish, or in other words, to know how to diagnosticate a disease with the least possible waste of time and with the greatest certainty, you ought to be trained. Though it must always be based upon accurate scientific knowledge, the diagnosticating of disease really is an art. To master it, you must practice it after you have been taught how; you must perfect your senses for the same end, and ought to possess some talent. What is called intuitively recognizing a disease is nothing else but the most perfect art developed in a natural talent; the mind reasons in such a case with a rapidity as to make its possessor unconscious of it, while his art enables him to jump, as it were, at a conclusion,

though, in fact, the same stages are gone through, but so quickly as to appear omitted. Even the most expert, however, if wise, will never rely upon such a diagnosis; he will apply the necessary tests to obtain the scientific proof.

You will have frequently observed, that after a question or two, sometimes by only looking at a patient, I recognized his disease. This intuitive knowledge I cannot communicate to you; you have to acquire it. But I can teach you the way to obtain it, and that is done by training. When you have practiced a certain manner of examining patients in hundreds or thousands of cases, you will gradually reach the zenith of the art, and become an accomplished diagnostician. But if you follow at the bedside in each case a different plan, a varying mode of procedure to arrive at a diagnosis, if you adopt no special method, you will obtain no result from your experience. Neither will you be successful if you should only rely on your art alone, without taking care to possess the necessary scientific knowledge. Indeed, your theoretical instruction regarding the etiology, pathology, diagnosis, and differential diagnosis of diseases should be complete in every respect, ere you commence to adopt a method of examining patients, and ere you try to perfect yourselves in the same. With this proviso I shall commence your training.

As it may be better at once to give you a practical demonstration of what I am about to teach you, and as it would be important for such a purpose to use for illustration one and the same case, let me ask you whether one of you gentlemen would be willing to serve as a clinical patient? Should there be one amongst you who is suffering from a pathological condition, he would be the more welcome.

(I. S., a member of the senior class, here rose, pronounced himself to be ailing from a morbid condition, and expressed his willingness to serve as clinical patient. At the request of the lecturer he stepped into the arena and took the usual seat of patients.)

Gentlemen, as Mr. S. has kindly volunteered to assist me in my efforts, I shall try practically to demonstrate on him what I have to say to you. He admits that he is suffering from a disease, of which I have no idea of what it may be. I must confess that the general impression which he makes upon me as diagnostician, teaches me nothing. I am, therefore, utterly unable to tell you beforehand whether he really is a patient, and what his disease. I am glad of this fact, as it will give me a still better opportunity to examine him strictly secundum lege artis, according to the law of the art.

The method which I shall adopt is one, with few alterations, pursued by all clinicians. Follow my advice, gentlemen, to examine every patient in exactly the same manner. Once more I repeat that such a procedure alone can make you accomplished diagnosticians.

As a general rule, when a patient enters your office, or when you visit him for the first time, at once study his face, his manner of walking, his mode of breathing, and everything that the eye can teach you. The flushed face of fever, the pale countenance of anæmia, the cachectic complexion of cancer, phthisis, morbus Brightii, heart disease, etc., the imbecile look of the idiot, the anxious expression of the drunkard laboring under the hallucinations of delirium tremens, the apathy visible in softening of the brain or in stupor, the Hippocratic face as the forerunner of death—all these and many others, too numerous to mention, will at once guide your thoughts in a certain direction, and cause you to concentrate your diagnostic efforts. Thus the existence of paresis or paralysis, and other motor disturbances, as observed when the patient moves about, the presence of affections of the respiratory organs, as evinced by the patient's breathing, and many other useful informations, all obtained from our inspection of the patient, ere we even accost him, may be gained in the manner indicated.

A patient is generally excited when confronted the first time with his physician. It is of great importance to allay this fear and anxiety, and we best reach this object by permitting him to talk of the affairs concerning others; but that we may obtain at the same time knowledge, which may aid us in the recognition of his disease, we usually begin with the family history. From it we learn the existence or non-existence of hereditary disease—whether cancer, tuberculosis, scrofula, nervous diseases, or any other ailment be hereditary in the family. The information thus gained is not only of value in a diagnostic point of view, but also regarding prognosis. For instance, a patient having been attacked by pneumonia comes to us with a part of the lung consolidated. The complete absence of tuberculosis in his family gives us strong hope of curing the lung disease by causing absorption of the inflammatory products, which induced the solidification of the pulmonary parenchyma, while the presence of a hereditary tubercular taint foretells the earlier or later breaking-down of the diseased tissue, the deposit of tubercles, if they are not already un-

dermining the consolidated lung, and the fatal issue of the case.

It would lead me too far to enumerate to you all the points that the family history may give us. The detailed study of the etiology of every disease will make you acquainted with them. I shall now make a practical application of what I told you, in the case of our friend S. As I have already explained to you, the mere inspection of him teaches me nothing, except perhaps, that the slightly bluish tint of his face denotes some circulatory disturbance. The fact of his wearing spectacles somewhat obscures the view. I cannot read the exact expression of his eyes, and it may be that I thus lose some information which I might have obtained otherwise.

"Is your father living, and if so, does he enjoy a good health?"

"Yes sir, he is a healthy man, and only occasionally complains of rheumatic pains, he having suffered once or twice from acute rheumatism."

Gentlemen, from this reply we learn only, that rheumatism seems to be in the patient's family. Rheumatism, I mean acute articular, is apt to give rise to heart disease. This, if present in the patient, is sometimes inherited by the offspring, but not necessarily. For the time being we store this information in our mind, proposing at the physical examination specially to examine that organ.

"Does your father ever complain of difficulty of breathing, or of palpitation, or of dyspepsia, or of giddiness, or has he ever had any other symptom of disease besides the rheumatic pains?"

"No, sir. As I said, he is always enjoying the best health, excepting his occasional rheumatic pains."

Treating our patient not as a student of medicine, I asked these questions to discover whether his father had been evincing any symptoms indicating organic disease of the heart. From the reply I infer that such has not been the case.

"What can you tell us of your mother?"

"She died in childbed, on the second day after delivery, after having previously been healthy. She had never complained of any illness."

In this direction the information also is a negative one. "Died in childbed," generally is a very uncertain answer, and when you receive it you must push your inquiry further to obtain the conviction that there really was no disease, to which the patient accidentally fell a victim at the time of delivery.

"Did any brothers or sisters, uncles or aunts, die of any hereditary disease?"

"No sir: they either died of acute diseases, as small-pox, pneumonia, etc., or in childhood, from diseases incident to this period of life, or their death was caused by an accident."

Again negative. In the case of a patient less educated and possessing no medical knowledge, I would have investigated the cause of each death that had happened in the family, and would not have been satisfied with the name of the disease, but tried, if possible, to obtain a description of its symptoms, especially if I had reason to expect important information; but here to save time I have made the inquiry in this general manner. As a rule be careful not to ask so-called leading questions; always try indirectly to elicit the desired knowledge.

"Are any of your sisters or brothers not in good health?"

"No; except one sister, who, during the colder season of the year, frequently contracts a bronchial catarrh, though otherwise she too is healthy."

These attacks of bronchitis are common, though when met with in ladies, who are not forced to be exposed to the vicissitudes of inclement weather; they generally indicate some hereditary tendency. Either scrofula, tuberculosis, or diseases affecting the circulatory apparatus, are apt to be present in the family of such women. This information we shall also store for a future occasion.

Not having succeeded in throwing any light upon the case by the family history, we will now proceed carefully to investigate the patient's own life, starting from birth and following it up to the present day; for the fact that he was delivered by the aid of the forceps—an information usually obtained from the patient's mother—or that he suffered from convulsions when an infant, and many other occurrences even during earliest childhood, may have a bearing upon his present condition. Next we find out his occupation, and here never be satisfied with such general answers as: laborer, mechanic, etc. Inquire after his real work. Thus, in a painter, you at once think of lead-poisoning; in a coal miner you would search for the coal dust in his lungs; in other occupations, as those of a weaver, a stone-mason, etc., you also have reason to be suspicious of a lung disease, as such is of frequent occurrence in this class of people; again, in another, the inhalation of mercurial vapor may have caused his ailment, or his working as a digger or plumber in damp, wet places, may have given rise to a malady, easily thus produced, and in a saloon or barkeeper you would at once think of the effects of

"treating." Then do not fail to inquire after the habits of a patient. Severe mental labor, carried on late at night, may at once show you the causing element; a drunkard is generally himself responsible for the disease from which he suffers, and individuals eating too little or too much cannot be surprised at their becoming ill. I once had a patient who complained of general lassitude, disinclination to work, sleeplessness, general loss of flesh, utter want of appetite, dyspepsia, constipation, and hallucinations, and of his feeling chilly. His health really seemed to have decidedly deteriorated, but notwithstanding the most searching medical examination, I could discover no lesion. The trouble had been lasting two months, and several physicians had vainly tried their skill. One day I spent over an hour with him, carefully going over his life during the last year, and investigating his habits. I then discovered that three months ago, when his wife with her children had left for England to visit some relations, the patient had commenced to eat in an irregular manner. This had caused dyspepsia, and to rid himself of it he followed the advice of a friend and adopted a diet which had cured the latter. In the morning he drank a glass of hot water, and ate two pieces of bran bread. At noon he made himself a cup of beef tea from Liebig's extract of meat (which, as well known, contains no nourishing material, but is only a stimulant), and with it he again took bran bread. At night one cup of milk and some more bran bread formed his supper. By the aid of this diet the poor man expected to regain his digestive powers, while in fact he was subjecting himself to a process of slow starvation. I put him on healthy, nourishing food, and ordered active outdoor exercise, and two weeks later he had gained twenty-three pounds, and was as healthy as almost ever before. This is an illustration of but one case. In others you will discover masturbation to be at the bottom of the disturbed health, while sometimes mental worriment, not sufficient sleep, too little fresh air, and sedentary habits, have produced the malady. When you have carefully learned everything about the patient, his occupation, habits, mode of living, etc., then inquire after every disease through which he has passed, beginning with those in childhood. For not seldom you will observe that a dropsy following scarlatina was never cured, or that a lung-trouble started with the measles in childhood; not to speak of those diseases which, as acute articular rheumatism, cerebro-spinal fever, etc., are apt but too often to leave some incurable malady as sequela. Syphilis may be in the system, or the individual may still suffer from malaria, whose first acute symptoms appeared some years previously. Sometimes he does not himself know this fact; then the locality in which he lives, and of which you are aware that its air is filled with the miasma of malaria, will tell you the tale.

You search, therefore, for every symptom or every disease which has attacked your patient at any time of his life. Be not satisfied with the name alone, but convince yourself by a description of the symptoms that the malady named really was the one from which he suffered. Then think of every possible sequela of such a disease, and not until you have satisfied yourself that there is no evidence of it in the system, let it drop from the consideration of the case.

That there are diseases specially characteristic of or belonging only to one sex, I scarcely need mention, and you will know that in the case of a female, in this inquiry after her personal history, you must not omit to examine the state of the sexual organs.

After you have elicited all the information that you can obtain regarding the ailments from which the patient suffered in his lifetime, you address yourself to the present disease. You try your utmost to learn its exact beginning, and then follow up its course to the present time. I cannot sufficiently impress you with the importance of this point. Frequently, if you can only obtain an exact description of the commencement of the malady, the diagnosis is established. Never attach weight to a name given; always ask for the symptoms, and thus recognize it. For instance, a patient tells you he had pneumonia a year ago, and dates his present illness from that time, while a description of the symptoms may convince you he had typhoid fever, or pleurisy, or only bronchitis, or something else.

What I have thus far told you concerning the patient's personal history, I will now apply to the case before us; for by this time, after I have been talking with him regarding the history of his family, he has gained confidence, and his initial excitement has vanished.

"What was the first disease in your life that you suffered from?"

"I have been remarkably free from the diseases of childhood, and with the exception of a slight cold I have never been ailing, until about three years ago, when my present trouble began."

"What did you occupy your time with after you ceased going to school?"

"I attended in the West to my father's cattle

ranche ; in other words, I have led the life of a cow-boy."

"How old are you ?"

"Twenty-eight years."

"You commenced the study of medicine about three years ago, and until that time you were enjoying active out-door exercise ?"

"Yes, sir; and from that time dates the beginning of my present illness."

"Did you ever have a chancre, or any indication of syphilis ?"

"No, sir; I never had any disease of the sexual organs."

"Were you ever affected with malaria ?"

"No, sir."

"Did your present disease commence suddenly or did it gradually develop ?"

"It crept slowly on me."

"What was the first symptom that told you you were not in the same health you used to be ?"

"A feeling of lassitude and disinclination to work."

"Describe to me the further progress of your ailment up to the present date."

"A state of general debility and anæmia gradually developed themselves ; I lost my appetite, and became listless. After this had lasted about a year, I somewhat improved under treatment, and returned to the mountains, but I soon found out that the quieter I kept and the less active exercise I had, the better I felt. The signs of anæmia slowly left me, but the general lassitude, the feeling of exhaustion after the least exertion, and an indescribable sensation of discomfort have continued until the present day and still annoy me."

"You are certain that you have not omitted any important statement ?"

"I have told you every symptom of my malady."

Gentlemen, from the personal history of the patient and from his description of his present illness we learn but the following : Until the time when he gave up his outdoor life and commenced the study of a profession his health was good, but after the symptoms of his disease had once made their appearance, the return to active outdoor exercise was not followed by an amelioration of the morbid condition. This fact seems to indicate to me, that probably for a long time there has been something wrong in his system ; there perhaps was some hereditary influence or some organic lesion, with which our patient was born, but which during his earlier growth or as long as he continued that mode and manner of life to which he was most accustomed, did not show itself. It always is an indication of a grave trouble, if a person, used to a country-life and becoming ill when leading a confined and sedentary existence, does not improve in the least when resuming his active exercise in the open air. Further I observed that Mr. S. was very cautious in his answers ; it seemed as if he tried to conceal something which he preferred to leave to my skill to discover. You see he smiles, a fact which confirms me in my suspicion.

When after the described mode of examination you have reached the point at which I have arrived in Mr. S's. case, you proceed to physical exploration, i. e., you investigate the condition of every organ. We may omit in this case an examination of the brain and of the spinal cord, for no indication whatever thus far points to a morbid condition of these organs. We will therefore at once explore the chest.

I find the percussion normal over both lungs, anteriorly and posteriorly, and auscultation reveals the normal vesicular murmur. We may say, therefore, that his lungs are healthy. The impulse of the heart is slightly heaving and can be felt in the fifth and sixth inter-spaces and over a greater area than is normally the case. Such an impulse denotes over-activity of the heart, and may be due to simple excitement of the organ. But applying my ear to the chest, to listen to the sounds of the heart, I find an abnormal condition, which promises an explanation of the morbid symptoms. I beg you to be as silent as possible for a few minutes.

Gentlemen, on carefully auscultating the heart I discover a murmur, whose seat of greatest intensity is to the left and a little above the nipple. It is best heard at the beginning of the second sound, in fact it precedes it, and it is, therefore, strictly speaking, a presystolic murmur. The lesion giving rise to such a murmur, is narrowing, constriction of the mitral orifice, or stenosis of the mitral valve. The second pulmonary sound is slightly accentuated, a fact generally met with in these cases.

The liver is somewhat enlarged, also a common occurrence in organic diseases of the heart. The spleen seems to be of normal size, while the conditions of the kidneys shall be inquired into by an examination of the urine, and the result be reported to you.*

Mr. S. suffers, therefore, from mitral stenosis. It is probable that he was born with it, for noth-

*Neither albumen, sugar, no trube-casts were discovered.

ing in his personal history points to an endocarditis, there having been no rheumatism nor other disease of the blood, nor an injury to the chest to account for it. The increase in the force of the impulse, which denotes an augmented action of the left ventricle, proves to me that there still is compensatory over-activity, but if the lesion had been acquired, there would be demonstrable hypertrophy, finally ending in dilatation of the organ. I do not doubt that there really is some hypertrophy, but it is so slight that percussion does not reveal it. Such a condition is generally met with only in cases born with the lesion, and we often observe under these circumstances an utter absence of all morbid symptoms until a more advanced age.

This case also teaches you not to expect in organic lesions of the heart any symptoms directly referring to the organ. Pain and palpitation are met with far more frequently in functional disturbances than in organic changes of the organ. You have seen in this case that the symptoms complained of were general in character, almost none indicating the existing pathological condition.

But even after you have established the diagnosis, as I did in this case, you must proceed in your examination of all the organs, for complications may exist which would either completely alter the diagnosis, or at least influence prognosis and treatment. Never be satisfied with the discovery of one morbid condition ; always investigate the whole system, and every part of it.

Here is no complication ; a mistake in the diagnosis cannot have happened.

"How long have you known that you suffered from this disease ?"

"Three years."

This fact, *i. e.*, the duration of the murmur, its constancy, proves its organic character. Besides, it is harsh and has a point of greatest intensity. It is neither an anæmic murmur, for such a one would be soft, be heard only at the base, would have long since improved under treatment, and other signs of anæmia would be present; nor is it one of those murmurs of which science has proven but recently that they simulate organic changes, viz., murmurs brought about by an alteration of the blood and a transient change in the size of the organ and the vigor of its action. Such murmurs, often simulating endocarditis, are heard at times in rheumatism. Here, as I said, the history of the case and the duration, constancy and harshness of the murmur, prove it to be due to organic change. Besides, the murmurs simulating morbid lesion usually take the place of the first sound.

In a similar manner you must always try to verify your diagnosis by excluding all diseases that might be mistaken for the one which you discovered. You next ask yourself concerning the prognosis of the case and its treatment. Mr. S. will know, as well as I, that he can never be cured of his complaint. But he may still live many years, until finally dilatation of the organ, or some other incident, especially concerning the lungs, bring about the final issue—though this may take so long that our friend may meanwhile have reached a high old age, and die of some other disease.

Regarding treatment, the patient should simply avoid everything that may overburden the heart. He should refrain from active exercise, but otherwise live according to hygienic rules. His case at present necessitates no special treatment. I might discuss more with you the therapeutic measures often called for by such cases; but as my object was to train you in the examination of patients, and as the hour is near to its end, I herewith close the clinic for to-day.

507 *Franklin street, Philadelphia.*

REPORT OF A CASE OF CONTUSION OF THE ABDOMEN, WITH SOME REMARKS.

BY LOUIS W. ATLEE, M. D.,
Of Philadelphia.

A. C., aged forty-seven years, American, country blacksmith, strong and robust, always enjoyed good health, with the exception of occasional attacks of cynanche tonsillaris. On Sunday evening, November 9, 1884, while handling a double-barrelled shot-gun, the load was unexpectedly discharged, the butt, in the recoil, dealing him a very hard blow in the right iliac region. The gun had the reputation of being a very hard "kicker," having knocked a boy "head-over-heels," as they said, the day before. Immediately after the blow he became so weak he had to be assisted to his room. He complained of being chilly, and had the appearance, it was said, of a man who had received a severe shock. Shortly afterwards agonizing pain in the belly came on, and he began to vomit. When I saw him, 48 hours after the injury, he was lying on his back, the legs drawn up ; the expression of face anxious and haggard (Hippocratic) ; the skin hot and dry ; tongue and mouth dry ; pulse 120, not very hard (there was some congenital aortic disease). The abdomen was very hard, and somewhat

swollen and tender to palpation over the seat of contusion. No external mark could be seen; percussion note tympanitic, except in right iliac region, where it was dull, not flat. Stomach rejected everything. The vomiting caused great pain; the vomited matters being regurgitated as it were. Respiration thoracic. The family physician said he feared invagination; he had given everything he knew to quiet the vomiting and move the bowels, but so far without success. He had given an enema of soap-suds and water, and gr. xx. calomel by the mouth, just before I arrived. I diagnosed a localized peritonitis, with some cause of obstruction of the bowel, probably from paralysis of the solar plexus, and advised giving nothing by the mouth but ice; enemas of laudanum and starch by the rectum; and to continue to use the poultices over the abdomen, as they had been doing before I saw him. At 7 a. m. the next morning (Wednesday), I saw him with my father, Dr. Walter F. Atlee; his expression was less anxious, complained of no pain, had slept a little, skin warm and moist, pulse 100, vomiting less frequent. Ordered milk and lime-water by the mouth, and to discontinue the enemas of laudanum and starch until the return of the pain. On Thursday evening he was better in every way. Milk and lime-water was retained. My father sent out one dozen of Spanish leeches to be applied over the seat of pain in the belly, but the family physician objected to their application on the plea of the patient being too weak, and they were never used. On the same evening the attending physician applied turpentine stripes over the abdomen, which he said relieved the intestines of much wind by the rectum. He also applied a fly-blister over the seat of injury. Neither myself nor my father saw him again until I was sent for in great haste November 19, 10:30 p. m. When I saw him soon afterwards he was lying on his back, legs drawn up, complaining of frightful pain in his belly, no pulse at wrist, vomiting, and every symptom of rapidly approaching dissolution. His physician told me he had been getting along very nicely up to that evening, with the exception of a slight diarrhœa, when he had the misfortune to get his feet entangled in the blanket wrapped around him as he was returning from the commode; he fell on his face on the floor, and immediately the symptoms which he had, now began. I said he had ruptured the intestine by the fall, and that I could do nothing. He was dead at 12:30 a. m., Thursday, November 20, just 10 days and 13 hours from the date of the contusion.

Post-mortem examination of the abdomen 92 hours after death. Body well preserved. No external mark of injury. Cuticle destroyed where blister was used. Skin of abdomen tense, umbilical region somewhat below the level of surrounding regions. On making the incisions, one from sternum to pubis, and a second at right angles to it above the umbilicus, gas escaped as soon as the peritoneal cavity was opened. Muscles of abdomen red and well developed. Adipose tissue three-quarters of an inch thick. The omentum was strongly adherent to parietes beneath the seat of injury. Intestines glued together by partially organized lymph, more or less injected. Between the parietal peritoneum and abdominal walls at the injured part, was a spot as large as the palm of the hand covered with extravasated clotted blood. In the intestine, lying to the right of the median line, midway between the umbilicus and pubis, was a jagged edged hole, large enough to admit the tips of four fingers; the intestine was empty and collapsed; the intestinal contents, the same as had been passed since the diarrhœa began, had gravitated into the flanks.

Not being permitted to make any further examination, we then closed the abdomen.

We have in the history of this case, a blow on the abdomen, followed by shock, peritonitis, symptoms of enteritis most probably from continuity of structure, a second injury to the abdomen, the fall, which was followed so closely by collapse and death in six hours—the post-mortem showing the intestine to have been ruptured.

In a monograph published in the "Guy's Hospital Reports" for 1858, 3d series, vol. 4, by Alfred Poland, entitled, *A Collection of Several Cases of Contusions of the Abdomen, Accompanied with Injury to the Stomach and Intestines*, I find the most thorough account of the subject.

I cannot do better than quote verbatim the opening paragraph: "A strike, kick or fall on the abdomen, a passage of a wheel over it, or a jamb between two opposing bodies, etc., must never be thought lightly of, and must always be regarded with suspicion and treated in a careful and judicious manner. Many a trivial blow in this region has resulted in unexpected and sudden death, although life has sometimes been prolonged for a short time in agony and suffering, terminating in collapse and death. This can be readily accounted for when we consider the numerous and vital structures contained in the abdomen; and also that these structures are enclosed within soft elastic parietes capable of great distension, while although readily able to resist

shock and extreme violence without injury to themselves, yet may allow the force to be transmitted and expended on the contents with dire effect, without an external mark."

A blow on the abdomen may cause sudden death (Sir Astley Cooper's case), or may be followed by simple traumatic peritonitis. Yet in by far the majority of instances of this class of injuries, some internal rupture or lesion always takes place, and in such cases life is seldom extinguished at once, but prolonged for a more or less short period, and ending fatally either in protracted collapse, or in fatal internal hemorrhage, or in subsequent severe peritonitis; few recover, and those only from circumstances of an extraordinary character. Injuries to the intestines may sometimes be followed by acute or chronic inflammation of the coats, causing what is termed traumatic gastritis, enteritis and colitis. One or all the coats of the bowel may be ruptured.

The effects of a ruptured bowel may be divided into two stages: The primary stage. The person feels the sensation of a blow; he gets up, but is soon seized with a peculiar depression of the nervous system, faintness, rigors, chilliness, and collapse. When the slight reaction ensues, the patient complains of the excruciating pain at the seat of injury, the features assume the Hippocratic expression, vomiting begins, the belly swells, and the abdominal muscles become hard and rigid. There may be retention of urine. These symptoms are caused by the effusion of the contents of the bowel into the peritoneal cavity, and will be modified accordingly as the bowel is full or empty, and the size of the rupture, and they will be more severe as the rupture is situated—the further from the stomach the less severe, and *vice versa*.

The secondary effects develop themselves in from six to twenty-four hours. These consist in all the symptoms of traumatic peritonitis. If immediately after the injury the abdomen becomes tense and tympanitic, it is a sure symptom that the bowel has been ruptured and allowed the air to escape.

The most general result of rupture of the intestine is death, which may come on during the primary stage of collapse, or from the subsequent peritonitis.

Recovery is possible, depending on the size and seat of the rupture and the condition of the bowel, but above all on the treatment adopted.

Repair may take place by the torn bowel adhering to some of the near structures, or the effusion may be circumscribed, abscess follow, a stercoraceous fistula resulting.

The most appropriate treatment is perfect rest on the back, nothing but ice to suck by the mouth, and opium to allay pain and the peristaltic action of the intestines.

Leeches may be put on during the inflammatory stage with benefit. Blisters are harmful. Warm fomentations are grateful to the sufferer. No food should pass the lips till after the fifth day; all food and stimulants necessary should be given in enemas.

If the symptoms of approaching dissolution are not too imminent where one is called to a case of ruptured intestine, could not the abdomen be laid open by an incision, the ruptured bowel sought for and sutured? When the rupture is very small, there will not likely be any extravasation, and the symptoms will not be so alarming, more especially if the rupture is in a part of the bowel distant from the stomach, and nothing has been given by the mouth. Such cases, no doubt are more numerous than believed, being looked upon as cases of simple traumatic peritonitis. But seeing that when the bowel has been torn sufficient to allow of extravasation, the result has been invariably fatal, with one exception (a case of circumscribed extravasation, followed by stercoraceous fistula, afterwards pyæmia and death), should not the only chance possible be given, *i. e.*, that of closing the torn gut? Life has been saved when death was imminent by removing a brust ovarian cyst, a ruptured extra-uterine fœtal cyst, or what is more to the point, by removing the cause, in obstruction of the intestine. If the small intestine were torn, the better course to follow would be to suture the rent, and clean the peritoneal cavity; if the large intestine, the edges of the rent could be united to the edges of the incision in the abdominal wall, establishing a fœcal fistula.

Hospital Reports.

ON THE TREATMENT OF ERUPTIVE FEVERS.

BY PROFESSOR DUJARDIN-BEAUMETZ.

Hospital St. Antoine, Paris, France.

Translated from advance sheets by Dr. Hurd, of Newburyport, Massachusetts.

Gentlemen: By their symptomatic aggregate the eruptive fevers constitute a natural group in the class of fevers, and the therapeutic indications which pertain to them deserve to arrest our attention for a short time. Of these so-called zymotic fevers, small-pox possesses especial interest on account of the prophylactic treatment peculiar to

this disease, and on this subject I have a good deal to say.

In consequence of the hideous aspect which the face presents when covered with pustules, the repulsive odor that comes from the patient, the unsightly cicatrices which the malady leaves behind it, and its extreme contagiousness, small-pox merits to be regarded as one of the most terrible of epidemics, and it is an important duty, on the first appearance of this formidable scourge, to endeavor by every means to limit its ravages.

Do not persuade yourselves, gentlemen, that this word ravages is a figure of speech, it is on the contrary the vigorous expression of the truth. When in fact small-pox smites populations which have had no protection or immunity from the disease, as is sometimes seen in certain races that inhabit the interior of Africa, or the Polynesian Islands, whole communities have been swept away by the lethal epidemic, and you can judge of the fatality of these epidemics, in recalling what happened only three years ago (in 1880), at the time of the arrival in Paris of a tribe of Esquimaux, which contracted small-pox during its peregrinations in Europe. All were attacked, and all succumbed. The observation of facts furnished a first means of preservation; it was remarked that persons who had once had the disease were ever after protected from its invasion, and either as the result of accident, or by a process of experimentation, inoculation for the prevention of small-pox came into vogue.

This inoculation or variolation has been, for many centuries, practiced by the Chinese, who make use of pock-scabs which they introduce into the nasal fossa. Then it was put in use in Circassia to protect young girls who were to be sold in the markets of Constantinople, and it is from this source that the wife of the English Ambassador, Lady Mary Wortley Montague, in 1721, obtained her knowledge of inoculation, which she communicated to the people of her country, whereupon this practice speedily spread over all Europe. But notwithstanding all the precautions that were taken, this variolation was not without danger, for inoculation from a mild case of the disease may engender small-pox in its most serious form, and although a real progress was made by inoculation, there was nevertheless a mortality of least one in three hundred. Jenner, who was as you know, a physician-inoculator in England, by his immortal discovery, substituted vaccination for inoculation, and from henceforth civilized man was in possession of a perfect prophylactic treatment for small-pox.

I shall not here discuss the value of vaccination. I am aware that there exists a small and uninfluential group of physicians who, under the name of anti-vaccinators, pretend that not only is the discovery of Jenner inefficacious, but that it is even dangerous; but their specious arguments have not lessened the preservative value of vaccine, a value to-day indisputable, and which all the countries of Europe and of the world make haste to recognize, by favoring the promotion of vaccination, and by making it a legal obligation. France has not yet enforced this obligation by legislative enactment, although it has done so in a round-about way, by making attendance at schools and military service obligatory, and in requiring a certificate of vaccination and of revaccination as a condition of admission to the public schools and the army.

I shall not examine here all the questions which the origin of vaccine has raised, viz., whether it comes exclusively from the cow or in the first instance from the horse. Whether cow-pox and horse-pox are anything but real small-pox developed in animals? Whether there is identity between human variola and animal variola? These are problems of experimental physiology which are far from being solved, despite numerous laborious investigations, in particular those of the veterinary school of Lyons and its chief Chauveau. Yes, it seems demonstrated that horse-pox and cow-pox are the small-pox of the horse and cow, but when you come to inoculate these animals with the human pock you obtain a product which gives you for the human subject not kine-pox but small-pox. The identity of vaccine virus and variola virus is only a hypothesis, but which will shortly become a scientific reality, thanks to the brilliant discovery of attenuated virus by our illustrious colleague Pasteur.

I cannot here resist the desire to say a few words concerning this doctrine, which, originating only a few years ago, occupies so great a place in the prophylactic treatment of diseases, and which has thrown so much light on the history of virulent and infectious maladies.

Carrying out the fruitful line of inquiry suggested by vaccination, Pasteur has shown that it is possible by special cultures of microbes, the supposed agents of contagion in virulent diseases, to change the character of the bacilli, or, to use the happy expression of Bonley, to domesticate them, and thereby create new varieties, which, while maintaining a protective power on the animal in which they have been inoculated, develop only a mild form of the original disease. This is what he has accomplished for chicken cholera, for swine plague, and especially for anthrax, or splenic fever, and to-day it is by tens of thousands that we count the flocks and herds that he has saved from this deadly anthrax by his experimental vaccination. It ought to be the same for small-pox and vaccine, but we have not yet found methods of culture for developing the vaccinal virus, and it is necessary that small-pox should undergo attenuation in the organisms of certain animals, such as the horse and cow, before the resulting virus can be truly protective.

Does the vaccine virus, you may ask, contain a microbe? Undoubtedly; and Klebs considers it as absolutely identical with that of small-pox. Chauveau, moreover, showed us in 1868 that vaccinal lymph deprived of its solid corpuscles, becomes inert.*

*Gluge, in 1838, was the first to describe in vaccinal lymph certain crystals which he believed to be the essential principle of this lymph. These crystals were nothing but brilliant corpuscles, which have been since described under the name of corpuscles of Gluge. Chauveau, in 1868, pointed out this capital fact, that when we deprive vaccine matter of the corpuscular elements which it contains, the vaccinal lymph becomes inactive. To obtain this complete separation, Chauveau employed the process of diffusion, and to a stratum of virulent liquid he added, carefully and slowly, a stratum of water; intermingling took place, and

You all know the methods of vaccination, and I need not here give you any rules for this operation, nor any description of the vaccinal eruption, only reminding you that it seems to-day demonstrated that the number of vaccinations and the intensity of the vaccinal eruption have a certain part in the protection conferred, and the statistics of Oppert and of Russell seem to me in this respect to be very conclusive. But one point on which I ought to insist is the necessity of revaccination; in fact, vaccine seems to lose its protective properties in about ten years; therefore, all the governments which have made vaccination compulsory have been careful to enjoin revaccination.

Of all the dangers which have been attributed to vaccine, there is but one which deserves your serious consideration: it is the possibility of inoculating syphilis when the matter is taken from a syphilitic subject. To-day it is perfectly demonstrated, and by observations, unhappily too numerous, which amount in our country to more than 120 cases, that vaccinal syphilis exists, and that too much care cannot be taken in the choice of the subject from whom vaccine matter is obtained. This consideration has had a good deal to do with the success which has attended animal vaccine, a kind of vaccination which Lanoix and Chambon imported from Italy in 1856 to our country, and you may see in this hospital the success which has been obtained by this bovine vaccination, to-day adopted by all the countries in Europe as well as in America. For my part, I consider animal vaccine just as good as human vaccine, with this advantage, that there is certainty of exemption form the danger of syphilis.

But now that the experiments of Villemin have been strongly confirmed by the discovery of the *bacillus tuberculosis*, one may ask if in this way tuberculosis, so frequent in kine, may not be transmissible by vaccine. So far we have had no proof of this fact, but it deserves to be discussed, and Warlomont, in his interesting work on vaccine, has devoted to the refutation of the possibility of inoculation of tuberculosis by animal vaccine, an interesting chapter, to which I refer you. Whether it comes from the infant or from the animal, vaccine matter may be preserved a considerable time. At our Academy of Medicine, where the humanized lymph alone is used, the vaccine is kept only incapillary and glass tubes. In countries where they make exclusive use of animal vaccine, which is more difficult of preservation, they employ the scabs, or dried pustules reduced to powder or paste, and my pupil, Dr. Crando, of Nice, has shown the activity and the easy preservation of these vaccinal preparations.

Vaccine constitutes, with hygienic means of isolation, the only prophylactic treatment of variola; all others are illusory, and even dangerous. The hygienic measures comprise an aggregate of means for the isolation of the patient—means especially necessary in our hospitals—and you see to-day the good effects of this isolation, thanks to the measures, incomplete it is true, which have been adopted by the Board of Public Charities and the Prefecture of Police, which have put at our disposal certain isolated barracks and special vehicles for the transportation of small-pox patients.

We know at the present day almost with certainty the mode in which the contagion of small-pox is received into the system, namely, by the respiratory passages, in most cases, if we can rely on the experiments of Zueger on animals. Brouardel had in fact previously shown us by examination of the air of small-pox wards, that this atmosphere was charged with numerous particles coming from desiccated variola pustules, and it is by the penetration of these particles into the respiratory passages that small-pox virus enters the blood. From these experiments, too, we may conclude that at the period of desiccation of the eruption we should redouble our efforts to prevent the dissemination of contagion. Unhappily, this is the period of the disease when the medical attendant finds himself most important, and till persons convalescent from small-pox shall be restrained by stringent legal enactments, we shall find it hard to prevent them from going abroad and carrying with them wherever they go, the contagious elements of the disease.

As for the treatment proper of small-pox I shall have little to say; during the invasion we can in some cases favor determination of blood towards the skin by means of sudorifics, and especially the spirits of mindererus. You will often have to combat the pain in the back, and the obstinate constipation, symptoms of the first stage. You can generally remedy the first by means of certain liniments (such as chloroform and spirits of turpentine of each 1 part, and liquid opodeldoc 8 parts); the constipation can generally be overcome by mild purgatives. Next comes the eruption; if it is discrete, if moreover the subject has been vaccinated, no active interference will be required; not so if the eruption be confluent, and all your efforts will be required, especially if your patient be a young female, to prevent the eruption from following its course, and causing disfiguring cicatrices. For this end various means have been proposed. Mercurial preparations, and in particular alum ointment and the emplastrum de y. vigo have the curious property of preventing the development of these pustules, and this abortive power has been utilized by covering the face of the patient with masks made of these preparations. Aran and Delioux, of Savignac, have proposed to substitute for these ointments a collodion made with corrosive sublimate; unfortunately, this collodion, however elastic it may be supposed to be, yields readily to the distension of the skin attending the eruption, and notwithstanding the real advantages of this method, I have had to abandon it and return to the primtive process of Zimmerman.

(*To be continued.*)

---

all the soluble parts of the serum were diffused through the water; the upper part of this mixture, when animals were inoculated with it, did not reproduce the vaccine. According to Hiller, the contagious principle of vaccine resides in certain pale opaque granules, some soluble in solution of potassa, others insoluble. Klebs believes that he has found the microbe vaccine; he claims that it is identical with that of small-pox; it has for dimensions $\frac{6}{10000}$ of a millimetre; it presents itself often in groups of four, whence the name of *micrococcus quadrigeminus*. Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting November 6, 1884. The president, R. A. Cleemann, M. D., in the chair.

Removal of Uterine Appendages for Menstrual Epilepsy—Recovery.

Dr. E. E. Montgomery exhibited the specimens and read the history of the case. Sarah H. æt. 17 yrs. was admitted to the Philadelphia Hospital, April, '84. She suffered from an attack of inflammatory rheumatism in childhood and began to have epileptic seizures in her thirteenth year; they were slight at first, but have recurred every month increasing in number and violence so that at present she is unconscious from ten days to two weeks out of each month. There has only once been a trace of menstrual discharge, and that for a single day only. There is no history of an chronic disease in the family, brothers and sisters are healthy. The patient was pale, flabby, anemic, poorly developed, and extremely nervous. The external genitals were but slightly developed, the uterus small, and no special tenderness over the pelvis. Iron, tonics and generous diet were given; the bromides were not well borne. Owing to her youth and the fact that she had not yet mensturated, it was deemed best to undertake to establish the menstural function and exhaust the anti-spasmodies before resorting to operative interference. The failure of all remedial measures was complete, and on September 13th the operation was performed; both ovaries and tubes were removed. No antiseptic was used about the wound. All the water used had been well boiled. Absorbent cotton was placed over the wound, which had been closed with silk sutures. The operation occupied thirty-five minutes. The recovery was uninterrupted until the night of the 26th of September, when she had four epileptic seizures. There were recurrences of slighter attacks during the next three nights, but they were shorter and during the intervals she was perfectly conscious. During the first four days of October, spells of staring with momentary unconsciousness occurred, becoming less frequent and lighter. A well marked convulsion on the night of Oct. 14th was followed by from one to four convulsions daily until the 29th. But they have not been so severe as before the operation.

Removal of the Parovarian Cyst—Recovery.

Dr. E. E. Montgomery presented the specimens, and related the history as follows: Miss A., æt. 30 years, native of England, married, never pregnant, has suffered from an enlargement of the abdomen for seven years. As it was first noticed a few months after her marriage, she supposed herself pregnant. Her menses have never been interrupted, now occur every three weeks, are very slight, and have never been excessive. She suffers from severe pain the week before menstruation, over the lower portion of the abdomen and through the hips. She suffers at other times from pain in the feet and legs, and from a sensation of weight. The tumor has been tapped some six times. The fluid was always of a pale straw color. The largest quantity removed at any one time was 40 pounds. Previous to its removal, her weight was 102 pounds. The last tapping was on June 27, 1884. She has had four attacks of peritonitis.

When first seen, last July, two weeks after the last tapping, the abdomen was swollen and tender to pressure; fluctuation was distinct. Since that time the abdomen has increased considerably in size, presenting a prominent tumor distending the whole abdomen, nearly symmetrical, but projecting slightly to the right side; circumference at umbilicus 32″; distance from symphysis to umbilicus 7″; to ensiform 13″; fluctuation distinct over the whole tumor; coughing projects the whole mass forward and downward. Her general condition is good. She is quite active.

Diagnosis.—A par-ovarian cyst.

Plan of Operation.—Exploratory incision; remove the tumor if possible, but if the adhesions were too great to permit that, then to open the sac, stitch it to the integument, and introduce a drainage-tube, and thus secure obliteration of the sac.

Operation.—October 9. Abdominal wound 4″; adhesions universal, but generally broken up without difficulty; no ligatures were needed. The intestines were not seen, being concealed by old inflammatory deposits. The right ovary was enlarged and was also removed. The wound was closed with seven sutures, and a glass drainage-tube introduced. Salicylated cotton in a thick layer was placed over the wound. Suppositories of morphia were used to control pain, which continued to a greater or less extent for two weeks, arising partly from inflammatory conditions, and partly from collections of gas in the intestines. The abdominal wound discharged freely—three ounces the first day. The drainage-tube was removed on the 13th, four days after the operation, but the discharge of bloody serum, pus, and flaky lymph continued for full two weeks later, when the wound closed entirely, and the patient was discharged.

Dr. B. F. Baer presented the specimens, and read the following report of a case of

Placental Polypus which Simulated Malignant Disease of the Uterus.

The patient was thirty-five years of age, married, and had two children at full term, the last twelve years ago. She has had several abortions since, but otherwise she has enjoyed good health Her mother died at the age of thirty-eight, of cancer of the uterus. In the early months of this year our patient first noticed that her catamenia were becoming too frequent, and were attended with expulsive pains and a fetid watery discharge in the intervals. The blood loss increased in quantity, and she soon began to show signs of failing health in pallor and loss of flesh. She would not permit a physical exploration until the latter part of July, when she had a violent flooding, with great pain.

Examination now revealed to Dr. R. Armstrong, of Lock Haven, Pa., whose patient she was, a healthy condition of the cervix and a normal os, but the body of the uterus was enlarged to more than double its natural dimensions; it seemed to be symmetrical and rather softer than usual.

The hemorrhage was controlled by ergot and rest. Although the grumous fetid discharge and the uterine tenesmus continued, she did not have another severe attack of metrorrhagia, probably because of her exsanguine condition, and the fact that she was suffering from septic absorption. Her temperature rising as high as 104° in the afternoon, she had distinct rigors. Her abdomen was tympanitic, and very tender to the touch. The physical condition of the uterus led the doctor to introduce two tents into the cervical canal on September 23. They were allowed to remain twenty-four hours, although their presence increased the violence of the symptoms. When the tents were removed, a rather soft, friable mass could be felt presenting at the internal os. This led to a fear that the disease might prove to be malignant. A severe colliquative diarrhœa now set in, and the patient's strength became so much reduced that nothing could be done except to administer remedies to check the diarrhœa and prevent collapse.

On the morning of the 25th, through the kindness of Dr. Armstrong, I saw the patient; temperature 103°, pulse rapid and weak. Stomach irritable, rejecting everything taken; bowels still quite reiaxed. Her face presented the ashy hue of malignant disease. The outlook was not favorable for an operation which would necessitate the dilatation of the cervix sufficiently to remove the diseased tissue, which evidently occupied the uterine cavity, but it was the only course to pursue. Ether was administered. The uterus was found retroverted and adherent to the floor of Douglas's cul de sac. The cervix was rigid, but slightly patulous. In view of the existing peritonitis, we concluded that it was best that I should endeavor to remove the contents of the uterus without a further attempt at dilatation, fearing rupture of adhesions and increased inflammatory action. I passed the wire loop of the écraseur through the os, and by careful manipulation luckily succeeded in guiding it over the tumor, and up to its attachment. Drawing upon the wire, it closed around the pedicle and severed it. The tumor was seized with a volsella forceps, and delivered. The index finger could now be passed into the cavity of the uterus. The pedicle was situated on the posterior wall near the fundus. The tissues at that point were soft and friable, but the remainder of the surface of the uterine cavity appeared to be free from disease. The stump was cauterized with nitric acid, and a two-grain opium suppository placed in the rectum. Convalescence was rapid and satisfactory.

On section and close examination, the specimen very much resembles placental tissue, and the microscope shows typical placental villi in its structure. It is the *placental polypus* described by C. Braun, in 1851, and somewhat resembles the *fibrinous polypus* of Kiwisch, who thought that these polypi might arise from long persistent hemorrhage, a kind of apoplexy of the womb; a large coagulum forming, the upper part consisting mostly of fibrine and adhering by a stalk to the uterine wall, whilst the lower consists of red, soft coagulum, having a coat of firm fibrin. Scanzoni does noes not admit this view. He contends that these are cases of abortion, and would therefore fall under the class of placental polypi (*Barnes*). My own experience argues with that of Scanzoni. These polypi cause profuse metrorrhagia, and and sometimes, as in this case, blood poisoning.

This case furnishes another strong argument in favor of the entire removal of the decidua or placenta after abortion. Who can tell how many lives are lost, or in how many cases the health is undermined by a neglect of this procedure? Death would inevitably have occurred in this case if the uterus had not been emptied. The patient may suffer for months or years, as a result of neglect. In this instance the fault was in the patient, for she had been properly advised by her physician. It is true that many cases escape without serious injury, but that does not prove that the principle and practice of immediate removal is not always the safe one; for here is a case where a neglected abortion had apparently passed off safely, but it almost destroyed the patient's life a long time afterward.

Malignant disease was properly suspected from the rapid development of such grave symptoms, from the general cachectic appearance of the patient, and from the sensation conveyed to the finger when touching the growth *in situ*. But when it was found that it had a limited point of attachment, and that the uterine cavity was healthy at all other points, this hypothesis was weakened; and when more careful examination of the specimen and investigation with the microscope showed it to contain placental villi, its benign character was assured.

Dr. Montgomery remarked that in cases in which partial dilatation of the uterine canal had been accomplished before the patient presented, the best instrument to continue the dilatation is the mechanical urethral dilator of Dr. A. H. Smith.

Hair-pin in the Uterus.

Dr. B. F. Baer exhibited a hair-pin removed from the uterine cavity of a patient sent to him by Dr. Pancoast, of Camden, N. J. The woman, believing herself to be pregnant, had tried to produce an abortion by inserting the pin by grasping the points and inserting the blunt end. The patient had obtained a view of the parts in a mirror placed upon the floor. The presence of the pin was readily detected by the uterine sound. He at first thought of dilating with tents, but the patient being greatly alarmed and very importunate, he used the steel dilator. One point of the pin became imbedded, in its descent, in the tissues of the cervix, and required dissection to release it.

Dr. Wharton Sinkler exhibited a hair-pin removed from the vagina of a patient who had tried to introduce it into the uterus to produce abortion. She had failed in her purpose, and had also failed to remove it from the vagina. The doctor found the points of the pin widely separated, presenting downward, and hooked into the walls of the vagina; by bringing the points close together, the pin was removed without difficulty. It had been in the vagina for some time.

Dr. Montgomery stated that, while a student, he had seen a hair-pin removed from a vagina. It was thickly encrusted with a calcareous deposit.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, November 13, 1884. The President, Dr. Shakespeare, in the chair.

Some Studies on the Micrococcus of the Pleuro-Pneumonia of Cattle.

By Thos. D. Dunn, M. D.

On September 25, 1883, through the kindness of Dr. Bridge, Assistant State Veterinary Surgeon, and Mr. Thomas Edge, Commissioner of Agriculture of Pennsylvania, I was invited to be present at an autopsy on some cows suffering from pleuro-pneumonia, their condition being such that recovery was deemed impossible. Mr. Edge ordered them killed.

As a description of the macroscopic and microscopic condition of the lungs was read before this Society a year ago, and as it would have no special bearing on the bacterian nature of the disease, a detailed account will be omitted.

Suffice it to say, the lung is completely solidified, the air-cells filled with effused blood, serum, and lymph, which usually extends into the small bronchial tubes. Portions of the consolidated lung and blood from the heart were placed in a bottle which had been thoroughly cleansed, and the bottle closed with a ground-glass stopper. These were examined microscopically by Dr. Geo. Martin and myself, and were found swarming with germs—*micrococci*. These little bodies, although seen distinctly with a power of 670 diameters, are best studied with a power of 1000. They are colorless, globular or oval in form, outline regular, and refractive power notable. The Brownian movement is marked; this is a tremulous motion not peculiar to *micrococci*. It is common to inorganic particles as well as minute vegetable and animal organisms. They do not seem to move in a manifest manner, independent of the currents of liquid in which they exist. They measure from a third to a half micro-millimetre, or from $\frac{1}{8000}$ to $\frac{1}{4000}$ inch in diameter. They are not dissolved by ether, alkalies or acids, and take the staining of aniline colors slowly. I have, however, succeeded in staining him by first treating with aqua ammonia, then with staining fluid and afterwards washing with a weak solution of nitric acid. They have recently been more satisfactorily stained by a two per cent. alcoholic solution of methyl violet. They multiply in nitrogenous culture fluids at ordinary temperatures by millions. They are generally separate, though sometimes united in pairs, and little cellular colonies forming distinct zoöglœa. From the fact of their being occasionally seen in pairs, it is reasonable to suppose that multiplication is taking place. They resist putrefaction, for the cultivation tubes started September 26th swarmed with them two months later. When the nitrogenous material is exhausted, their growth is stopped, and the remain in a latent state, as it were, until additional food is given, or they are transplanted into fresh fluids. After the tubes stand a few weeks, the membrane formed on the top sinks to the bottom, and the liquid above clears. That they are not dead, but only in a state of repose, is evident from the fact that they multiply anew when inoculations are made from them, but less rapidly than inoculations from more recent cultures.

Dr. J. J. Woodward, U. S. A., presented at a meeting of this society, in 1861, a pleuro-pneumonic lung, and mentioned certain "spores of fungi" found in both the healthy and diseased lung, but he did not describe them. These "spores of fungi" are probably the *micrococci* under consideration. Aside from this, I have not found any record of them, but unfortunately I have not had access to the literature pertaining to this subject.

The following culture experiments were made with the serum virus taken from the diseased lung. The culture fluid consisted of extract of fresh beef, made by chopping it fine and pouring over it hot water. After maceration the juice was expressed and the extract boiled for several minutes. It was then filtered, and again boiled, to thoroughly destroy all germs. It was then placed in culture-tubes, which had been washed in a solution of corrosive sublimate, and afterwards boiled. The tubes were closed by absorbent cotton, which was sterilized with corrosive sublimate and the application of dry heat. After the culture fluid in the tubes had cooled, a minute quantity of the serum was introduced by a small knife whose blade had been heated in a spirit lamp. The tubes were then placed where the temperature ranged from 90° to 120° Fahrenheit. On examination of these tubes on the 28th, the liquid was found turbid, a thin membrane formed over the surface, and there was a slight deposit. Under the microscope, thousands of *micrococci* were seen. From this cultivation a second was made, and after standing 48 hours the surface membrane, cloudiness of fluid, and slight deposit appeared, and myriads of *micrococci* were found. From this a third generation was started, in which appeared a few *bacilli*—the first discovered.

They are very active, colorless bodies, measuring from three to five micro-millimeters in their long diameters, and from one-third to one-half in their short. Their movements are at times rapid; again they are in a state of repose. Sometimes one will remain a long time motionless, then suddenly dart across the field of the microscope, setting many of its fellows in motion, who seem to catch the spirit of the active *bacillus*. At one time they advance with the rapidity of an arrow, then retreat or describe circular lines. It was noticed in those cultivations in which the *bacilli* were found the surface membrane was thicker and more tenacious. In cultivations conducted at a lower temperature the development of *micrococci* was not so rapid. Fearing that some atmospheric germs might have been introduced with the culture, other cultivations were begun from the second generation, in which no *bacilli* were found. The culture fluid was boiled at intervals, to kill germs that might develop from spores not destroyed by previous boilings, and as a further test non-inoculated tubes were placed by their side. In forty-eight hours the former were swarming with both bacilli and micrococci, while the non-inoculated ones remained clear for ten days. These subsequently developed germs after inoculation.

A second series of observations was commenced with fresh virus obtained October 4. The first and second cultures were pure, but in the third *bacilli* appeared, and in the fourth they had greatly increased. It is difficult to explain the relation these forms bear to each other, as to whether the *bacilli* are organisms developed from the *micrococci*—the latter being in a sporal stage

of their growth—our investigations will not justify a positive answer. Koch has determined that the *bacilli* of anthrax develop veritable spores, and they in turn develop *bacilli*. Several other observers held this view, and according to the investigations of Koch, Cohn, and Pasteur upon the development of bacteria, it is probable that the spores of *bacilli* and other bacteria are identical with *micrococci* in form, aspect, and behavior toward chemicals. In those diseases in which certain *bacilli* and *micrococci* are found to be the virus, it is impossible to distinguish them from harmless ones by their microscopical appearance; that is, a specific disease germ can only be determined by its effects on living organisms. The *micrococcus* of pleuro-pneumonia, so far as present observations go, is identical with that of diphtheria, chicken-cholera, and the recently-discovered *micrococcus* of scarlet fever. It is further found that this germ of virulent matter rendered harmless by attenuation does not differ microscopically from the unattenuated, which destroys life. I have made no inoculations on animals with the micrococcus of pleuro-pneumonia, but a few cows have been inoculated by others without any reference to a special virus or cultivation of the germ, and the disease was transmitted. However, several experiments have been made in view of destroying the germ, the results of which I will briefly state. A tube containing cultivated *micrococci* was boiled, and from it a second was inoculated. In 36 hours the tube contained many *micrococci* showing that the germ is not destroyed at 212°. A culture fluid to which had been added ten per cent. of alcohol was then inoculated. No *micrococci* had developed one week later. One and a half per cent. of benzoic acid with borax to dissolve was then added to a culture fluid: neither *micrococci* nor *bacilli* had appeared six weeks afterwards. Another culture was started, to which was added corrosive sublimate in the proportion of one-half grain to the ounce. In three weeks there were no traces of germ life. To test the influence of cold on these organisms, a tube containing cultivated germs was frozen, and from this sterilized liquids were inoculated. In forty-eight hours they contained myriads of *micrococci* and a few bacilli. A portion of diseased lung was frozen, and inoculations from this grew in about the same time. It was afterwards found that the cotton, which had been sterilized by heat and corrosive sublimate had been inadvertently exposed to old cultivations and decomposing organic substances, and it is possible that bacteria were introduced by it. When I repeated these experiments, it was found that while inoculations from non-frozen virus develop *micrococci* in a few hours, it requires several days for sowings from frozen specimens to grow in the same culture fluid and under the same conditions of temperature. Whether they were not exposed to cold long enough to destroy the germs, or the influence is only sufficient to render them inactive, further investigations will be required to determine. It is my impression that cold will check the spread of this contagion, but not destroy it altogether, and that when the disease once attacks an animal cold will have no influence upon it, though it may prevent the spread of the infection to others in the same herd. The power of medicinal agents to control the disease seems to be very feeble. It would appear that corrosive sublimate, alcohol, and benzoic acid arrest the growth of these germs, but whether doses sufficient to destroy them can be administered without endangering life our veterinary surgeons must determine.

Dr. Shakespeare said that he had read of two attempts within the past year or two, to isolate the micrococcus of this disease. Bruylants and Ferriers united in an attempt of this kind, and have reported their observations in the *Bull. de l'Academie Belgique*, 1880, to the effect that they found a micrococcus constant in the pleuritic and alveolar exudate. More recently, the report of Poels and Nolen, of Rotterdam, has appeared, in which they describe the isolation and culture of many generations of micrococci.

Moreover, they have compared them with those of human pneumonia, claiming their identity morphologically, and with regard to their mode of growth; and a further identity as to the results of inoculation, their experiments showing that pleuro-pneumonia in cattle has been produced by inoculation of the cultures of micrococci from human croupous-pneumonia as well as by inoculation of cultures from the pleuro-pneumonia of cattle. The latter report is published in the *Centralb. f. d. Med. Wiss.*, No. 9, 1884.

Dr. Formad said that this micro-organism had also been seen and described by Veterinary Surgeon Lyman, who had presented a very elaborate report to the Department of Agriculture. Dr. Quile, both a medical man and a veterinary surgeon, also had worked in pleuro-pneumonia for two years in the Pathological Laboratory of the University of Pennsylvania, always finding the micrococcus present, and in pure cultures kept up for many generations, he had not observed any other bacteria. He had inoculated two calves with large quantities of the culture, and had failed; whence he had concluded that the micrococcus was not the cause of the disease. He remarked as fact in favor of the micrococcus being the cause of the disease, that these organisms are chiefly found in the lymph, and that in pleuro-pneumonia enormous lymph-spaces are developed in the lungs, which are filled with a grumous liquid containing micrococci in large numbers, while the contents of the alveoli contain very few micrococci, but swarm with other bacteria.

Dr. Dunn, in his concluding remarks, said that one point of interest had been omitted in his paper, which was, that the cattle from whom the specimens had been obtained had been first knocked down, then bled to death, and buried *superficially* in a field, through which flowed a stream from which neighboring herds were watered. In a few weeks the disease appeared in these cattle also. As to the literature of the subject, he had not access to sufficient to familiarize himself with any investigations made by others. Some experiments with reference to inoculation have been successfully made in France and England. The lymph was introduced into the body and tail, and was found to protect the animal from the disease. When the virus was inserted into the tail with proper precautions, the mortality from the operation was less, being from one to two per cent. It was also found that when the tail became greatly inflamed, it could be removed to

limit the inflammation, and still afford protection to the animal. Inoculated animals did not communicate the disease.

[A specimen of tumor of the bladder was presented by Dr. J. H. Musser, the account of which has been, by his desire, held for future publication.]

(*To be continued.*)

EDITORIAL DEPARTMENT.

PERISCOPE.

Mitral Stenosis and Insufficiency.

The following interesting case is reported by Dr. T. C. Railton in the *Lancet*, November 15, 1884. He says:

The following notes of a case of mitral disease may be useful as showing how very important symptoms may be sometimes masked by other conditions, and the diagnosis thereby rendered difficult. They show as well, in a tolerably typical manner, the picture of the heart's gradual restoration from asystolism to comparative well-being, with the disappearance concurrently of all the symptoms depending upon the former state.

T. W——, aged thirty-two years, book-keeper, came under treatment on March 10. His father died from heart disease and bronchitis at fifty-four years of age, but there was no further history of rheumatism or heart disease in the family. Although always troubling himself a good deal about business and working hard, the patient had considered himself to be a healthy man until quite recently, with the exception of three attacks of bronchitis which he had suffered from during the past winters, the cough, however, disappearing when the warm weather came. So far as he knew, he had not been under the care of a medical man; he had never suffered from rheumatism, from shortness of breath, nor had he lost flesh. During the last month he had taken cold and had a cough, with occasional hæmoptysis and shortness of breath; but he continued at his business until two days before coming under treatment, when his increasing disorder compelled him to remain in bed. When first seen, he was found to be suffering very considerably from dyspnœa, which was aggravated by the slightest exertion. He had to be propped up in bed, and was much distressed by a constant hacking cough, bringing up a sputum tinged with blood. He had no signs of congestion in the face, being quite pale. He was perspiring freely, and there was a sour smell present, like that of acute rheumatism. He had, however, no elevation of temperature and no joint affection. There was no œdema of the extremities nor any perceptible ascites, but the abdomen was considerably swollen over the region of the liver. His fingers and toes were very decidedly clubbed at their ends. On examining the chest, it was found to be well-developed, with both sides equal; the percussion note was almost tympanitic, except at the base of the right lung posteriorly, where there was comparative dullness. A few rales were to be heard scattered over the chest, and bronchial breathing in that part where the dullness existed. The superficial cardiac dullness was found to be perfectly normal; the apex beat was diffused and weak, but situated somewhere about the nipple-line in the fifth interspace, at which spot a faint presystolic thrill could just be perceived. On auscultation at the apex the first sound was remarkably short and flapping, and was not followed by any second. There was an exceedingly short and slight roughness to be heard immediately preceding the first sound, which might almost have escaped attention had not the presystolic thrill pointed out its nature. At the base there was a reduplication of the second sound; in the aortic area it was weak, in the pulmonary area it was but very little stronger. There was no tricuspid disease discoverable. The liver was found to be uniformly enlarged, but there was no pulsation or any great degree of tenderness. The dullness in the right nipple-line was six inches and a half in depth. The spleen was apparently somewhat enlarged. The urine was scanty and loaded with urates; it contained a considerable quantity of albumen. The treatment adopted was to keep the patient perfectly quiet, to supply him with a nourishing diet, more particularly Benger's peptonized beef jelly, and to administer half an ounce of the Pharmacopœial infusion of digitalis every three hours.

I need not occupy space by detailing the daily progress of the case; it will be sufficient to mention briefly the changes in the various organs implicated. The dyspnœa began to abate in the course of twenty-four hours after beginning the digitalis, and had entirely left him in three days. The sputum tinged with blood disappeared at the same time. The sweating was noted as much less by the fourth day, at which time also the liver dulness was found to be diminished. On the sixth day the size of the liver had become quite normal. At the same time that portion of the right lung which had been compressed regained its normal resonance and breath sounds. The urine was clear and free from albumen on the third day. As regards the heart, although its action continued to be irregular during the whole attack, and in fact has remained so since, the pulse became stronger in the course of two days, and with the improvement in the nutrition of the cardiac walls the sounds underwent the following modifications: On the third day the murmur at the apex, from having been genuinely presystolic in rhythm, was noted to have changed so as to occupy the whole of the ventricular pause, the second sound being still absent. It was very rough in character. The next day, the rhythm and everything else remaining the same, the roughness had changed to a loud rumble. On the fifth day the aortic second sound was to be heard at the apex for the first time, and was immediately followed by the rumbling murmur,

which, however, no longer extended quite to the beginning of the first sound, thus becoming post-diastolic in rhythm. The second sound at the aortic cartilage was noticed to be louder than before. On the sixth day a faint systolic murmur accompanying the first sound was heard just at the apex, not traceable to the axilla or back, the post-diastolic murmur remaining as before. In this condition the heart has remained up to the present time, when the patient has been compelled to resume his occupation. All the sounds are stronger; at the base the aortic sound is normal, the pulmonary sound accentuated.

Remarks.—The absence of abnormal cardiac dullness might have rendered the diagnosis obscure, if the other symptoms had not pointed so strongly to cardiac insufficiency. No doubt the enlargement of the right ventricle and left auricle is masked by an emphysematous condition of the lungs, the result of the previous attacks of bronchitis. The insidious advent of the disease, without any previous history of rheumatism, and its long existence (as shown by the clubbed ends of the fingers and toes, and by the extent of the mischief in the heart itself), without having attracted attention, hardly require comment, both of these circumstances being common in this form of valvular mischief. It is worth noting, however, that after a long period of immunity the rupture of compensation was brought about with the greatest rapidity by an attack of cold. I would draw attention to the alteration in rhythm of the obstuctive murmur under the influence of rest and digitalis. At first a true presystolic murmur, it changed so as to occupy both diastolic and presystolic periods, and later the diastolic period only. These changes were coincident with an increase in the strength of the walls of the left ventricle, as shown by the improvement of the aortic second sound, its conduction down to the apex, and by the appearance of the systolic mitral murmur. It is quite reasonable to suppose that by strengthening the ventricular walls their diastolic power will be increased in the same ratio as their systolic power; and this permits us to make use of Dr. Broadbent's hypothesis that the post-diastolic rumble may be produced by the blood being strongly drawn from the left auricle, through the narrow mitral opening, during the active dilatation of the left ventricle. This will account for the production of the diastolic or post-diastolic murmur, but will not explain the absence of the presystolic portion of the murmur at a time when other signs showed the heart to be acting strongly. It would seem that the increased power of the left ventricle to fill itself during the diastolic period resulted in a condition modifying the vibrations of the mitral valve during the presystolic period, and so rendering them inaudible. A question of great interest in mitral stenosis is the almost characteristic loud and short first sound. It has been aptly compared with the second sound in quality, and appears to owe its shortness, like the latter, to the fact that it consists of a vibration of the valves unaccompanied by muscular bruit. The absence of tone in the walls of the left ventricle particularly is to be explained by the small amount of blood which has habitually reached it in a long-standing case of mitral stenosis, like the one we are considering, and may thus account for the imperfect contraction of the muscle. As regards the loudness of the sound, sometimes so extreme that one cannot hear it without a stethoscope eight or ten inches from the chest, it is difficult to explain unless we accept Dr. Broadbent's suggestion that, "it is due to imperfect distension of the ventricular cavity, and the consequent absence of resistance at the beginning of the systole."

The Comma Bacillus.

The *Lancet*, November 29, 1884, contains the following:

We have received the following "conclusions" arrived at by Dr. E. Van Ermengen, after some researches upon the comma bacillus of Asiatic cholera, communicated to the Microscopical Society of Belgium on October 26th. They will be seen to traverse most of the points in dispute, and to accord with Dr. Koch's results.

1. In the intestinal fluids of patients attacked with cholera (eight autopsies and thirty-four examinations of stools) there exists an organism identical with the comma bacillus discovered by Koch.

2. Its curved shape, its **S**-shaped, and chain-like groups, due to juxtaposition, and its occasional formation of slightly wavy filaments, give an assemblage of microscopical characters which render it easily recognized from pathogenic micro-organisms hitherto known.

3. It is more or less abundant in the choleraic products according to the period of the disease and the time of examination. In two rapidly fatal (*foudroyants*) cases it occurred in the intestinal contents almost in a pure culture. In one case of short duration, where the patient had succumbed with very marked algide phenomena, there were very few comma bacilli to be found in the intestinal fluid. They disappear from the darker stools of the reaction stage.

4. It would have been very important to search for them in the dejecta of patients attacked with so-called premonitory diarrhœa, but our investigations were not brought to bear on this point.

5. In the single case of algide cholera, where microscopic examination failed to detect numerous comma bacilli, a culture of a small quantity of the intestinal contents on soiled linen in a damp chamber yielded an incalculable number of characteristic comma bacilli in twenty-four hours.

6. Microscopical examination of dejecta can suffice to establish the diagnosis of Asiatic cholera when preparations containing the different forms of comma bacilli in excess are obtained.

7. Bacterioscopic research supplies the deficiencies of microscopical examination in cases where the comma bacilli are scanty, and are even not found with certainty in the preparations. The characteristic aspect of their colonies, studied under a low power (150 diam.), renders them easy of recognition. The practical value of these culture processes on the glass slide in nutrient gelatine (10 per cent.) is well shown by our experiments. Mixtures of a very small quantity of the cultivation product with a considerable amount of putrefied blood, stagnant urine, fæcal matter, hay infusion, etc., yield preparations where the typical colonies of comma bacilli have

been detected with readiness in the midst of most varied vegetation.

8. The study of the morphological characters of the comma bacilli at different stages of development, cultivated in various media, chiefly in chicken broth and fluid serum, shows that they should be classed with true spirilla.

9. The most varying conditions of temperature and medium have not resulted in the discovery of a stage of spore formation; and their want of resistance to drying proves that they do not produce permanent germs.

10. Gelatine cultures cease to be inoculable six or seven weeks after having been sown. Agar-agar cultures still contain living organisms after eight to nine weeks.

11. The temperature most favorable to their development seems to be that of from 25° to 37° C. Below 16° (between 8° and 15°) they are still developed, but with difficulty.

12. Their phenomena of growth and multiplication are extremely active. In from two to three days they completely liquefy many cubic centimetres of coagulated serum.

13. The curved bacilli of the saliva, discovered by Miller (March, 1884), and believed by Dr. Lewis to be identical with the choleraic comma bacilli, do not develop in gelatine, 10 per cent.

14. The cultures of the organisms, to which MM. Finkler and Prior attribute the production of cholera nostras, are impure. That which I examined contains two kinds of bacilli. Their mode of vegetation and the appearance of their colonies in gelatine differ from those of the comma bacilli of Asiatic cholera. One of them gives to the cultivating medium a very characteristic greenish-blue fluorescence, which is wanting in the pure cultures of the comma bacilli.

15. Attempts at inoculation of the cultivation products have so far yielded very encouraging results in some species of animals, such as dogs, rabbits, and guinea-pigs. Three out of four guinea-pigs died in two or three days after the injection into the duodenum of one drop of a culture (fourth day) of the comma bacilli in liquid serum, after the method pursued by MM. Nicati and Rietsch, of Marseilles. The cadaveric appearances were those of cholera, and the intestinal fluids contained large numbers of comma bacilli.

16. The pathogenic action of these products of cultivation is very likely due to a zymosis, to an unstable albuminoid compound. Corpuscles of fresh human blood placed on Ranvier's heated platinum, and brought into contact with a drop of a serum-culture, present characteristic changes wholly comparable with those described by MM. Nicati and Rietsch in their observations on the blood of choleraic cases.

17. The discovery of the comma bacillus is of the greatest importance in the diagnosis of choleriform attacks of doubtful nature which occur at the commencement of epidemics, and for the resort to more effective prophylactic measures which this early diagnosis allows.

18. The employment of bacterioscopic methods in the diagnosis of cholera does not offer any great difficulty in practice, and it would be very desirable, in view of the serious threats of an invasion of Belgium by cholera, that a sufficient number of physicians employed in the sanitary services should be initiated therein with the least possible delay.

Carcinoma of the Stomach in a Child.

In the Pathological Society of London, Nov. 18, 1884, Dr. Norman Moore showed sections of the stomach taken from a girl, aged 13 years, who was brought to the hospital with extreme anæmia and slight anasarca of the face, hands, and legs. Her heart's action was very feeble, and she had a loud systolic murmur, audible at the left base. Her pulse was of very unequal beat, and a systolic thrill was to be felt over the whole cardiac area. She had no albuminuria. Besides her anæmia, her chief symptoms were repeated attacks of cardiac distress. She never vomited blood, but two days before her death, complained of pain in the abdomen, and was slightly sick once or twice. An enlargement of her spleen was felt. She died five weeks after admission.

Post-mortem—A new growth, of which sections were shown, was found at the cardiac end of the stomach, close to the œsophagus. The mass was about three inches across. Its periphery arose from the mucous membrane, and was of the same color, but its central parts were ragged, dark colored, and very tense. On section it was red, with paler stripes. The outer part of the growth was adherent to the liver, but did not penetrate it. There was a little recent peritonitis apparently due to a slight tear at the periphery of the growth. No glands and no other organs were infiltrated. There was a very old, and perhaps congenital dislocation of the right hip joint. The heart was greatly dilated. It contained several adherent, softened, ante-mortem clots, and there was an adherent thrombus in the left jugular vein. The microscopical characters of the growth were those of a carcinoma with somewhat wide trabeculæ, with extensive mucoid degeneration of the cell contents, but no degeneration of the trabeculæ, and with hemorrhages into several parts of the growth. Three distinct stages were visible in the growth. In the least degenerate, numerous cells of an epithelial type were collected in large alveoli. In another, advanced mucoid changes were observable in the epithelial cells, and in some cells the nuclei had disappeared. In the most degenerate parts, almost all the nuclei had disappeared, leaving a mass of mucoid material intersected by traces of the cell boundaries. In all three parts the fibrous trabeculæ of the carcinoma remained unaltered. The early age of the patient was a remarkable feature of the case: it was one of the earliest, if not the very earliest example of cancer of the stomach (with microscopical determination) hitherto recorded. The cancerous mass was less dense than such new growths in the gastric wall usually were, but resembled many such cases in the absence of secondary deposits. The child's paternal grandmother died of carcinoma of the descending colon at the age of 53, in 1878, and was examined post-mortem by Dr. E. D. Wallis, of Leiston, Suffolk. The growth was not examined microscopically, but there could be little doubt that it was a true carcinoma, and his case might be regarded as an example of the law of heredity that peculiarities tended to

appear at an earlier age in the progeny than that at which they occurred in the ancestor.

Rupture of the Heart.

Before the Glasgow Pathological and Clinical Society (Oct. 14, 1884), Dr. J. Lindsay Stevens exhibited three specimens of spontaneous rupture of the left ventricle of the heart.

1. The first specimen was obtained from the body of a man who had been treated in the cutaneous wards of the Western Infirmary for a somewhat generalized eczema. There had been no complaint whatever of any heart trouble, and death was sudden, while the patient was alone in the bath-room applying his ointment. The pericardium was distended with red serum, and a large clot was moulded on to the surface of the heart. A linear, ragged tear, about one inch in length, was present in the free margin of the left ventricle, about midway between the auriculo-ventricular septem and the apex. The branch of coronary artery going to this part of the heart wall was completely obstructed by an aneurism filled with clot, and both arteries were highly atheromatous. Fatty degeneration was only very slightly present; the muscular tissue in the neighborhood of the rupture was much softened. Dr. Stevens was still engaged investigating the histological changes in this case, but had not yet quite made up his mind as to their true nature.

2. The second case was sent to the Western Infirmary Museum by Dr. Yellowlees, of Gartnavel. It was obtained from a woman aged 70, who had been long insane, and who was in her usual health until the time of her death, which was sudden. There was a large irregular aperture of a generally oval shape, and an inch in long diameter, situated in the anterior wall of the left ventricle, close to the septum. The wall of the heart was somewhat bulged around it, and the edges of the aperture were everted. Fatty degeneration was distinctly present, but not extreme or sufficient of itself to cause rupture; and the left coronary artery, in addition to being atheromatous, was plugged by a thrombus and so rendered impervious.

3. This case was also furnished by Dr. Yellowlees, and was one of sudden death. On the external aspect of the left ventricle, near the base, there was a longitudinal aperture about $\frac{3}{4}$ of an inch in length. The internal opening was much smaller—only $\frac{1}{8}$ of an inch in diameter, and its edges were quite smooth. In all probability the rupture in this case had been due to aneurism of the heart-wall.

Night Blindness.

Before the Ophthalmological Society of the United Kingdom (Oct. 9, 1884), Mr. W. Adams Frost read notes of two cases of night blindness. The first was that of a painter, aged 34, who had had six attacks of night blindness, each coming on whilst he was painting white houses in the spring, the weather, except on two occasions, being very bright. Each attack lasted about a fortnight, and disappeared under treatment by rest, tonics, and use of eserine. Vision during the attacks was $\frac{2}{3}\frac{0}{0}$, and the visual field was normal. The patient was somewhat anæmic, but there was no history of any illness. He was in receipt of good wages, and had not been underfed. He had never had any symptoms of lead-poisoning, nor had he ever been out of England. The second was that of a lamplighter, aged 19, who for six weeks had been engaged in painting the lamp-posts on country roads in excessively bright weather. After three weeks' painting, he suffered severely from pain and lachrymation. Three weeks later he suddenly found that he could not see one evening, and this inability to see in a dull light continued until his visit to the hospital two weeks later. His vision then, in ordinary daylight, was normal ($\frac{2}{2}\frac{0}{0}$ and 1 J.); the visual field was normal. He presented no signs, and had had no symptoms, of lead-poisoning. He was treated with tonics and instillation of eserine, and recovered in about five weeks. A month later he had a relapse, from which he recovered in about a fortnight. Since the previous attack he had been following his ordinary occupation of lamp-lighting.

Mr. Walter H. Jessop asked Mr. Frost whether he had noticed any patches on the conjunctiva in his cases?

Mr. Frost replied in the negative, and Mr. Jessop said that, in three cases coming under his own notice lately, suffering from night blindness, patches were present in both eyes, looking like small bubbles of air, and easily scraped off. On these dry patches were numerous bacilli of uniform size; these facts had been noted by Snell and others. Two of the cases were under Mr. Nettleship's care at Moorfield's, and the third was under Mr. Jessop's care at the Paddington-Green Children's Hospital. Two were children underfed, one nearly starved, and the third case was an adult man, suffering from albuminuria. Artificial cultivations from two cases showed the same characteristics, especially as to slowness of growth. In the third case, the dry patches disappeared at the same time as the night blindness.

The Graver Fevers of Child-bed.

Dr. W. C. Neville contributes an article on this subject to the *Dublin Jour. of Med. Science*, November, 1884, which thus concludes:

1. There are a variety of puerperal fevers, but no one "puerperal fever," properly so-called.

2. Some of the less serious fevers result from local inflammations, combined with some degree of toxæmia.

3. Various exanthemata—notably scarlatina—may occur about the period of child-bed, and are then manifested in a more or less blurred form, though they can usually be recognized by specific peculiarities. Such fevers are apt to be complicated by endogenetic toxæmia, septic poisoning, or septic infection.

4. There are two chief types of puerperal toxæmia accompanied by fever—the infective and non-infective.

5. The non-infective form is the result of septic poisoning, and comprehends the greater number of sporadic and, in its uncomplicated form, more remediable cases of puerperal fever.

6. The infective form results from heterogenetic infection—septic, erysipelatous, diphtheritic, etc.—and includes the greater number of serious

child-bed fevers, especially such as assume what is usually known as the "epidemic" type in the practice of hospitals or individuals. The succession of cases is kept up by the actual transfer of the infective contagia (almost certainly consisting of pathogenic bacteria or their spores, contained in the unhealthy secretions), by hands, instruments, etc., from one patient to another. The initial case of such a series may be due to the infection of the patient with septic material derived from the juices of some corpses—especially such as are but lately dead of some malignant infective disease—from gangrenous, sloughing, erysipelatous, or diphtheritic wounds, etc.

7. There are exceptional cases in which, thugh the symptoms and progress resemble closely those of the infective fevers, no foreign source of infection can be discovered. Some of these cases may originate in usually severe traumatisms or crushing occurring during labor, followed by sloughing, etc.; others in an intensification of a pre-existing catarrhal or gonorrhœal inflammation of the genital passages; and others, again, in the local and neighboring inflammatory consequences of the retention within the uterus of decomposing portions of the placenta.

Operative Treatment in Intestinal Obstruction.

In the first Harveian Lecture (*Brit. Med. Jour.*, November 22, 1884), Mr. Thomas Bryant lays down the following rules for operative treatment:

1. Laparotomy should be undertaken as soon as the diagnosis of acute intestinal strangulation is made. There should be no delay allowed for the formation of a specific diagnosis of its cause. It should likewise be proposed in all cases of acute intussusception, and of chronic, which have failed within three, or, at the most, four days, to be releived by other treatment.

2. In all operations of laparotomy, it is to the cæcum that the surgeon should first advance, since it is from it he will obtain his best guide. If this be distended, he will at once know that the cause of obstruction is below; if it be found collapsed, or not tense, the obstruction must be above. Adhesions or bands are, moreover, more frequently near to, or associated with, the cæcum, than with any other part of the intestinal tract. It is also in the right iliac fossa that the collapsed small intestine, in cases of acute strangulation, is usually to be found; and, with this as a starting-point, the surgeon will have less difficulty in tracing up the intestine to the seat of strangulation than if he begins at a distended coil, when it will be a matter of chance whether he travels away from or towards the special object of his search—the seat of obstruction.

3. In a laparotomy, when the strangulated coil of bowel is gangrenous, it should be brought out of the wound, and the gangrenous knuckle resected. The proximal and distal ends of the resected bowel should then be stitched to the edges of the wound, and an artificial anus established.

4. Nélaton's operation of enterotomy should be undertaken in all cases of intestinal strangulation, when laparotomy is rejected or seems inapplicable, as well es in cases of intussnsception in which the invaginated bowel canuot readily be released. It should be performed in the right groin, or, rather, right iliac fossa.

5. If laparotomy succeed, the cause which called for it is removed, and the normal action of the bowel is restored. If resorted to early, and as a rule of practice, it is probable that it would be more successful than the treatment by opium, inflation, or purgatives, which has hitherto been in vogue.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A remarkable case of successful œsophagotomy for the removal of a foreign body (a gold tooth plate) is reported in a reprint before us, by Dr. Leroy McLean, of Troy, N. Y.

——The success which at times attends the judicious hygienic treatment of acute urania is illustrated in a paper from the *Alienist and Neurologist*, by Dr. A. Nellis, jr., of Willard, New York.

——Dr. W. O'Daniel, of Bullard's, Ga., in an article from the *State Transactions*, argues that the plaster splint is preferable to all others, "because accidents can be successfully treated with less trouble to the physician or surgeon in charge, with less risk and with a greater degree of comfort to the patient; and certainly so in preventing displacements, which, if not discovered and corrected before union, sometimes leave life-long deformities, which frequently disable patients who remain standing indices against competent and skillful surgeons, who are frequently considered by the unprofessional responsible for the ignorance or negligence of nurses and the obstinacy of patients themselves; and last, but by no means least, the patient is saved a long term of service in bed, on his back, from probably a simple fracture of the leg."

——Dr. Thos. F. Wood, of Wilmington, North Carolina, publishes a pamphlet on "The Work of Medical Progress in North Carolina." As Secretary of the State Board of Health, he speaks with full knowledge, and his report is a cheering one.

——A contribution to the study of muriate of cocaine in ophthalmic surgery comes to us from Dr. C. J. Lundy, of Detroit, Michigan.

BOOK NOTICES.

Transactions of the Medical Society of the State of Pennsylvania. Vol. xvi. Published by the Society. Philadelphia, 1884.

This is a handsome, well-printed volume of 622 pages, and its contents are every way worthy of the care with which they have been issued.

There are a large number of original papers, the result of close personal observation and heedful reasoning.

It would not be worth while to give the list of them here. We have already done more than that in our report of the meeting of the society, to which this volume refers. They cover a wide ground in both medicine and surgery, and there are few special branches but are represented by one or more articles which offer a real increment to knowledge.

Several of the articles are illustrated, and doubtless many of them will see the light in other media, where they will be more accessible to the general public.

The excellent feature of receiving reports from county societies is kept up, something over twenty counties responding to the call, and the part of the publication they furnish is by no means the least valuable. We trust that these will be fostered as much as possible, as this is one of the most potent plans of securing general interest in a State society.

The Story of My Life. By J. Marion Sims, M. D., LL. D., edited by his son, H. Marion Sims, M. D. 8vo., pp. 371. New York, D. Appleton & Co., 1884.

When the great Gœthe set about writing his autibiography he boldly and honestly called it "Truth and Fiction;" and it would be better were this title given to ninety-nine out of every hundred biographies composed by the subjects themselves. As a rule, they could not write the truth about themselves were they to try, and as a still more general rule they will not try.

Dr. Sims' autibiography is a pleasant book, reminding one in its vivid portraitures and in its strong personality of those delightful old "Memoires," which the French of the last century had such a genius for compiling. He tells the incidents of his interesting career with the zest of a romance writer, and the occurrences and conversations of his early life are set forth in a vigorous style.

The medical reader will turn with the greatest interest to chapter xiv., in which the writer describes the progress of his discovery of the operation for vesico-vaginal fistula. It is told with all his usual realism of description, and with a remarkable poetic license of the imagination. Those who are acquainted with medical history know perfectly well that Dr. Sims did not originate the operation, nor did he even introduce any important improvement in it. The silver suture, the shot fastening, the method of exposing the lesions—all these had been practiced and published before the date of his asserted discovery of them, and if he did not know of them, it was because he had not read the current literature of his profession.

We do not wish to detract an iota from any just claim of Dr. Sims', but we are equally unwilling that he or his admirers should detract from the just claims of others; and we cannot refrain from expressing our astonishment that Dr. J. N. Toner, undoubledly the most thorough medical historian of our country, in the biographical sketch which he appends to the volume, should pass over this unfounded claim in silence.

The history of this operation has been published in various quarters, and in its general introduction and popularization, Dr. Sims did a master's work, and one that cannot be too highly praised; but his claim to having originated it must be regarded as a case of self-delusion, or unconscious memory.

A Practical Treatise on the Diseases of the Ear, including a sketch of aural anatomy and physiology. By D. B. St. John Roosa, M. D., LL. D. Sixth edition. 8vo., pp. 718. New York, Wm. Wood & Co., 1884.

Among the standard works on aural diseases, the above-mentioned treatise has long held one of the highest places. It is complete, largely the direct result of the author's own studies, written with the intention of making his subject clearly comprehended, and by careful and frequent revisions, kept well up to the times.

The present edition has undergone a thorough revision, involving both many alterations and a number of additions, materially increasing its bulk, and likewise adding to the interest it will have for the advanced student and the specialist. The illustrations are numerous, and are well printed. Quite a number of them have been prepared especially for this edition from anatomical specimens in the possession of the author or his friends.

Elements of Surgical Diagnosis. By A. Pearce Gould, F. R. C. S. 18mo., cloth, pp. 584. H. C. Lea's Son & Co., Philadelphia, 1884.

This volume belongs to the series of "Manuals for Students of Medicine," which is in course of publication in London. They are, as we have said before, far superior to most such series, and the present issue is no exception to that rule. It is clearly the work of an experienced surgeon, who has his material well in his mind and can express himself tersely and clearly. No practitioner in surgery can read it without deriving great benefit from its many suggestions.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM,* which we publish.

It is, in fact, a supplement to the *REPORTER,* being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address
DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE BEGINNING OF 1885.

With the beginning of the New Year it is an old and a good custom to lay out one's plan of labor, and to make certain projects and determinations for one's action during the next twelve months.

What is the habit for the individual guidance may profitably be applied to the professional life. There is always a good, a better, and a best employment of one's time in his profession. It is not enough to measure this by the one standard of pecuniary gain. However necessary this may be, it is not the only nor is it the highest common measure of action. In our avocation especially, there are other and more urgent duties than that of simply putting in the time to the greatest money profit. In fact, it may be said that he who looks solely at the main chance will often miss it through the consequences of this narrowness of his visual range.

There are many things besides this which will occupy the hours of the enlightened physician. He will pursue some investigation the results of which will accrue to the benefit of his fellows; he will impart the experience he has gained to the world through some of the avenues which now offer themselves in such abundance; or he will engage actively in some of the measures which are always in discussion in medical societies, and which look toward the benefit of the profession as a body or of the public at large.

It would be well if every physician at the close of his career could point to some such purpose clearly defined and successfully prosecuted, and call it the fruit of his labors. Were this a general rule the amount achieved in the aggregate would be great, and the rate of progress would be vastly increased.

Now that the young year is beginning, with so much in it in store for all, with so much in sight that urgently asks the doing, we make these suggestions, trite ones, if you please, but ever timely ones, so long as there remains need for their adoption. They are appropriate at all periods, but particularly so when we enter upon a new epoch in our lives.

THE REPORT OF THE SURGEON-GENERAL.

The annual report of the Surgeon-General contains a number of items of wide interest.

One of these is the comparative mortality and liability to disease of the white and colored soldiers. Among the white it was 12 per 1,000 of mean strength, and among the colored it was 10 per 1,000.

It is interesting to note that not only is this the lowest death-rate yet reached among colored troops since their organization, but it is the first time that the rate has fallen lower than that for white troops; the usual average difference being 3.2 per 1,000 of mean strength, in favor of the latter class.

The admission-rate for malarial diseases which, in the aggregate, constitute 11 per cent. of all diseases and injuries reported, is 10 per 1,000 lower than for the previous year. Contrary to accepted opinion, malarial diseases have shown themselves to be more frequent among the blacks than the whites, the admission-rate for the former being 62 per 1,000 higher for this year, and 14 per 1,000 higher for the previous year. It is believed that this apparent increase can be explained by the fact that all regiments of colored troops, except one, are, and have been, serving for many years in an especially malarious region—the Indian Territory, the State of Texas, and the Southern part of Kansas, together with the States of Missouri and Arkansas, an area which, while it contains less than 20 per centum of the strength of the army, furnishes nearly 50 per centum of all cases of malarial diseases reported.

Comparative ratios for white and colored troops who have been stationed together for an irregular series of years, between 1876 and 1880, inclusive, within the region indicated, show, as a rule, a greater prevalence of malarial diseases among whites; but they also show that departures from this rule are of occasional occurrence, and are usually due to explainable causes. The average difference between the two races for malarial diseases was, during the years noted, 76 per 1,000 of mean strength in favor of the colored race.

The colored troops present a higher rate than white troops for syphilitic and other venereal diseases. On the other hand, their comparative freedom from intemperance continues to be of interest.

With regard to consumption, while there appears to have been no material difference between the two races in the rate of admission during the year, the combined rate of loss by deaths and discharges has been somewhat in favor of the white troops.

Typhoid fever was unusually prevalent during the year. It appeared principally in barracks, and could be traced to defective drainage and sewerage, bad ventilation, overcrowding, and impure drinking water. There does not seem evidence that it was conveyed from one post to another by the transfer of the soldiers.

The progress of the medical and surgical history of the war has been slow, partly owing to the long sickness and final decease of Dr. J. J. Woodward.

Brief necrological notices of the medical officers deceased during the year are appended.

TREATMENT OF CHOLERA-DIARRHŒA BY ENTERO-CLYSMA.

Prof. Arnaldo Cantani, of Naples, introduced, in 1870, the treatment of intestinal catarrh by entero-clysma, viz., by injections, carried high up in the canal. According to the nature of the disease, the character of the injected material varied. When this year the cholera ravaged in Italy (our readers will remember that the Asiatic epidemic appeared with a remarkable severity in that country), Prof. Cantani concluded to try the same mode of procedure in the prodromic stage—the diarrhœa of cholera. As he seems to have succeeded admirably, we bring in the following, a synopsis of an article which he published on the subject in the *Centrlbl. f. d. Med. Wissensch.*, November 1, 1884:

To determine the nature of the fluid to be injected C. thought of the alkaline reaction of the intestinal discharges in cholera, and of the fact, established by recent investigations, that all acids

were inimical to the existence and propagation of the comma-bacilli, which are met with in such large numbers in recent cases of Asiatic cholera. He could not employ carbolic acid, as the quantity to be used would have been dangerous to the life of the patient in case of the absorbing power of the mucous membrane of the bowels being retained. He had often succeeded in curing recent and chronic intestinal catarrh, chronic ulceration of the bowels, and infectious dysentery, with tannic acid; and he concluded, therefore, to make a trial of the same remedy in the premonitory stage of diarrhœa in cholera, especially as tannic acid is capable of preventing putrefaction, and possesses, therefore, more or less disinfecting power.

In many hundreds of cases the result of these tannic acid injections has been so favorable, that C. is convinced that their general adoption at the beginning of cholera-diarrhœa during an epidemic of cholera would lead to the total prevention of the development of the grave attacks, or at least, reduce their number to a minimum.

The following formula was employed by C.: Tepid water (which has previously been boiled 2000.0), tannic acid 5. 0—6. 0—10. 0, gum arabic 50. 0, laudanum ♏ 30 to 50. C.'s assistants preferred an infusum florum chamomillæ to water.

In some cases, where the entero-clysma could not be administered according to C.'s method (3 to 4 meters high up in the bowel), the same favorable results were obtained by the use of a common syringe, if the cases were seen at the earliest beginning of the disease. In more advanced stages the common syringe did not suffice.

Where in a family some member was suffering from cholera, any diarrhœa attacking other members of the same family were at once looked upon as cases of premonitory cholera-diarrhœa, and treated according to the method described. Generally one single application of the entero-clysma (at a temperature of 38° C.) succeeded in stopping the discharge; the characteristic cholera-diarrhœa at once ceases, and a free interval of from 8 to 12 hours follows; after each fresh discharge the procedure is repeated, and usually four to five such injections suffice to put a stop to the great loss of water, which the blood suffers, to insure a continuance of the urinary secretion, and to induce at once the febrile stage without any typhoid complications, so that the algid stage never sets in in cases thus treated.

For the purpose of determining the manner in which tannic acid acts in these cases, C. instituted a series of observations in his clinic, and these demonstrated the fact that while the remedy does not effectually kill the comma-bacilli, it completely prevents their propagation and multiplication, and deprives them of all power of locomotion during at least twenty-four hours. This fact explains the action of tannic acid in the prodromic stages of the epidemic.

While it is possible that other remedies, thus locally applied in C.'s manner, may have a still better effect, C. believes that in tannic acid, if administered as described, we at least possess a drug which makes an abortive treatment of Asiatic cholera a possibility. These statements of Prof. Cantani carry with them the more weight, as his experience at the time of the epidemic in Italy in more than 300 cases, showed in each case invariably the same favorable result, not one single case of those thus treated developing into a graver form of the disease.

Notes and Comments.

General Precautions in the Administration of Anæsthetics.

While we are frequently taught that we must be very careful in the administration of anæsthetics, yet it is well that this caution should be constantly impressed upon our memories, hence we deem it well to reproduce the conclusions with which Dr. George Eastes concludes his paper in the *Brit. Med. Jour.*, November 29, 1884. They are as follows:

1. The patient should have no meal (except in cases of extreme feebleness) for four hours beforehand, to avoid the tendency to vomiting. A little brandy or ammonia may be given with some water fifteen minutes before the operation if the patient be an adult and chloroform be selected.

2. The anæsthetist should endeavor to reassure the patient by a kind, gentle manner, which may

calm an agitated heart, and induce easy respiration.

3. No tight-fitting garment or band should be left around the chest or abdomen.

4. All artificial teeth must be removed from the mouth.

5. The anæsthetist should examine the heart-sounds and pulse before the operation. This precaution may seem superfluous, in most instances, but in a few cases may put the administrator on extra guard.

6. The patient should be placed in the recumbent posture, with the head but slightly raised. This is particularly important when chloroform or any other cardiac depressor is used.

7. The anæsthetic should be applied in the manner most suitable to the vapor used, about which I have already sufficiently spoken under the heading of each drug that I have mentioned.

8. The surgeon should not commence his procedure before the patient is fully narcotized ; not alone in severe operations, for many simple procedures, such as the reduction of dislocated joints and strangulated hernia, and the diagnosing of tumors of the abdomen and pelvis, require complete muscular relaxation for their successful attainment.

9. It is a golden rule never to give more of the anæsthetic than is necessary for the production of sufficient anæsthesia for the operation that has to be performed. Since every extra degree in anæsthesia is an advance along that road whose extreme goal is death, the patient should be taken no nearer the dreaded end than is quite requisite, as all the steps passed have to be retraced. Besides, as the gap separating the patient from death becomes lessened, it may easily arise that, in extreme narcosis, one extra and apparently trivial event, which in health would be quite inoperative to cause a fatal issue, may determine the patient's career.

10. Wherefore, lastly, as the work which the anæsthetist performs depends for its successful result on such a number of nicely-balanced conditions, his whole attention, during the few minutes of his employment, should be concentrated upon the case. He must watch the respirations, the pulse, the countenance, and the general condition of the patient. He should not be observing attentively the steps of the surgeon's procedure, otherwise he may fail to notice the first sign of danger in the patient, and the life, for which he is chiefly responsible, may be jeopardized before it is recognized that it is in peril. Moreover, the anæsthetist may rely upon receiving more than full recompense for all his care in a decreased number of mischances and a welcome table of good results.

Caries of the Cricoid Cartilage.

The following remarkable case specially adapted to mislead the most experienced diagnostician is published in the *Annal. des Malad. de l' Oreille et du Larynx*, 1884, 7, and is of great interest on account of its diagnostic importance :

A dealer in wines, æt. 38, had for two months been losing flesh decidedly without his having any cough or apparently suffering from any disease, except a certain hoarseness in his voice and a pain on deglutition, which later showed itself whenever the patient swallowed solid food. Four weeks later, nightly attacks of suffocation and a daily increasing dyspnœa were added to the symptoms. Except a slight difficulty on divergence of the vocal chords, nothing abnormal could be detected; neither revealed the examination of lung and heart any morbid condition. Within one week the difficulties greatly increased, and the examination again made with the laryngoscope now revealed immobility of the chords in the median line. Tracheotomy, at once performed, procured some ease, but a rather intense pain, felt at both sides of the larynx, still persevered. About a month later, the vocal chords moved somewhat better, but had become red and slightly swollen, and the same was observed of the external arytænoid region. The general emaciation of the patient progressed in such a degree as to make a skeleton of him, and the pain on deglutition increased in severity. The sputum commenced to contain tubercular bacilli, and over the left apex crepitant rales were perceived. Six weeks later, the patient presented a sad picture ; the wound made by tracheotomy assumed a malignant aspect ; the lower margin of the thyroid cartilage was laid bare, being ossified and necrotic ; there was complete aphonia, and the vocal chords and the aryfold were infiltrated.

The patient died, and the post mortem examination revealed the following: Both lungs were thickly sown with tubercles, and the original disease, caries of the cricoid cartilage, was discovered. It formed an ossified, rarified, and purulent mass, which penetrated into the œsophagus and had caused a thickening of the arytænoid region. It is possible that the life of the patient might have been saved, if the exact diagnosis of the condition of the cricoid could have been made at the very beginning, and the cartilage had been removed.

The Protean Character of Gout.

As of interest in connection with the remarks on this subject by Mr. Hutchinson (see Vol. 51, p. 741) we are pleased to note two corroborative cases which Dr. A. Conan Doyle reports in the *Lancet*, November 29, 1884. In these cases, the grandfather was thoroughly gouty; the father had skin affections without any other gouty symptoms, and the third generations (the cases in question) exhibited eye symptoms and nothing else. The most striking feature of these cases was that they improved rapidly under the use of colchicum and alkalies.

Removal of a Tumor from the Brain.

The *Brit. Med. Jour.*, November 29, 1884, reports that on November 25, at the Hospital for Epilepsy and Paralysis, in London, a tumor was successfully removed from the substance of the brain. The case was under the care of Dr. Hughes Bennett, who, having diagnosed an encephalic morbid growth of limited size, and localized it in the upper part of the fissure of Rolando, requested a surgeon to trephine the skull over the suspected region. This was carried out by Mr. Rickman Godlee. A mass of glioma, of the size of a walnut, was extracted from under the grey matter of the upper part of the ascending frontal convolution. Up to the present time (November 29), the patient has progressed favorably in every respect.

Retroversion of the Gravid Uterus.

Before the Harveian Society of London (October 16, 1884), Dr. Amand Routh read details of five cases of retroversion of the gravid uterus, two of which, when first seen, were complicated with resulting retention of urine; the bladder in these cases exactly simulating the objective signs of unilocular ovarian cyst. Seventy ounces of urine in the one case, and fifty ounces in the other, were drawn off. Reduction was easily effected in all the cases, without subsequent abortion occurring, and with immediate relief of the symptoms of backache, nausea, and frequent micturition. The importance of early diagnosis and treatment was insisted upon.

Dr. Champneys referred to a case recently seen by him, in which an India-rubber bag was introduced into the rectum, and distended with water under a pressure of four feet, with excellent results.

Chorea in the Aged.

While not common, yet chorea does occur in old people, and since it is likely to be mistaken for senile trembling, we deem it well to call attention to the cases which Dr. Robert Saundby reports in the *Lancet*, November 29, 1884. He reports three cases which he has observed himself, and refers to nine other cases that have been reported by different authors. Dr. Saundby considers that the symptoms are sufficiently characteristic to render the diagnosis easy, and, according to his views, when it is mistaken for senile trembling, it is because the physician does not know that chorea may occur in old people. While not sure of the pathology, yet he is inclined to believe that it is not merely a functional disease, but that there is some actual structural change, such as small hemorrhages in the corpus striatum. In regard to treatment, he has little of value to say. He has found bromide of potassium of some little use, and in one case, which recovered, sulphate of zinc was used. In all of the cases reported, the general health was very bad. For such feeble old people, cod-liver oil is one of the best remedies.

Salicylate of Sodium in Malaria.

Not long since, salicylate of sodium was highly recommended as a preventive in yellow fever. This fact induced Dr. von Kirchbaur, assistant physician of the 16th Infantry Regiment of the Prussian Army (*Allg. Med. Centr. Zeit.*, November 5, 1884,) to try the remedy in a case of intermittent fever which had baffled his skill for several months. Every possible preparation of the Peruvian bark, all its alkaloids and arsenious acid—these administered in large doses and enormous quantities — had been tried in vain. The patient was a woman, and the fever had the quotidian type. K. advised her as a last remedy to take 16 grains of the salicylate of sodium in lemon-juice about an hour or two before the expected febrile seizure. After the very first dose the attack was much milder than it had generally been; the second seizure omitted, and after the seventh dose—daily one such dose having been taken—the intermittent fever had left and not returned at the time of publication, three months later.

Several months ago we published in the Medical and Surgical Reporter a series of observations regarding the effect of salicylate of sodium, and mentioned at that time that it was a very safe remedy, more reliable than quinine as a febrifuge, almost tasteless, easily soluble in water, and never causing tinnitus aurium. We then recommended more extensive trials in malaria, and we again do so to-day.

Thallin—Another Antipyretic.

The *Medical Press*, November 26, 1884, thus refers to it:

"Dr. von Jaesch, of Vienna, has recently stumbled on still another synthetic antipyretic, which he introduced to the notice of the Society of Physicians of Vienna, on October 31st, the chemical name of which is zetrahydroparachinanizæ. The name no doubt is an excellent one for ceremony and great occasions; but recognizing that life is short, and not to be all spent in pronouncing names, he has mercifully given it the shorter one of thallin, by which it will be sufficiently well known if it proves to be worthy a name at all. He has already employed it in 86 cases of pyrexia of various kinds, viz., pneumonia, typhoid, erysipelas, measles. The fever was cut short with certainty, and without any disagreeable bye-effect, but the effect upon the course of the disease was in other respects nil.

"In doses of $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$ gm. the temperature fell several degrees. Of the various salts of the drug enumerated by him—sulphate, tartrate, hydrochlorate—he recommends the first-named for clinical purposes, and suggests that it may well be employed when all other antipyretics have failed."

Skim Milk in Diabetes Mellitus.

Dr. J. Lindsay Porteus does not seem to think that the treatment of diabetes mellitus with skim milk has received the attention that it deserves, and he therefore publishes a paper on the subject in the *Edinburgh Medical Journal*, December, 1884.

Skim milk diet as recommended by the late Dr. Donkin has, in his hands, proved very successful. To do good, it requires resolution and much self-denial on the part of the patient to throw aside all the good things of this life, and live on skim milk, and nothing but skim milk. At first the patient eagerly catches at the chance of relief from the excessive thirst, parched skin, and other tortures, and steadily determines to take the skim milk, but, as a rule, on the fourth or fifth day he begins to tire of it, and, as in one case under his observation, the sight of it made the patient vomit. Fortunately in some cases a little kindly encouragement helps him to overcome his dislike, and with renewal of the remedy a cure is effected. He has seen much good, but never a cure by the codeia treatment. The drowsy and languid feeling which it causes, are sources of great annoyance and depression to the patient. The sp. gr. and sugar are often decreased by it, but the latter never entirely leaves. The same remarks hold good with regard to opium.

To Render Oral Suction After Tracheotomy for Diphtheria Harmless.

In view of the fact that Dr. Rabbeth recently died in England from diphtheria contracted by sucking the tracheotomy tube, Dr. John W. Ogle writes to the *Lancet*, November 29, 1884, offering the following suggestion, which seems to have a ring of good sense about it.

He suggests that such suction would be rendered free from any risk, provided that a piece of some very thin, soft, and pliable material, such as extremely delicate cambric or silk (or so-called "grenadine" or "gossamer"*), three or four inches square, were laid over the windpipe and so adapted as to form a small pouch or sac over the orifice made therein, which should be received into the mouth of the operator before the suction was practiced. The character of the tissue or material would permit of the movements of the lips and tongue appropriate to the act of sucking; and the diphtheritic stuff would be almost as easily drawn into the sac contained in the mouth as if nothing had been interposed between the windpipe-orifice and the cavity of the operator's mouth. It would doubtless be, also, advantageous if the substance forming the sac or pouch into which the diphtheritic material would be sucked were well moistered by some suitable antiseptic liquid, such as a solution of boracic or salicylic acid, or a spirituous solution of thymol or diluted oil of eucalyptus. By such a procedure as the above described the diphtheritic films and fluids aspired into the mouth would not, in any case, come into direct contact with its lining membrane; and in this way danger to the operator would be entirely obviated.

Intra-Uterine Therapeutics.

The question of intra-uterine therapeutics, or the proper drugs to introduce into the cavity of the uterus has been a very much-discussed question. Dr. Lombe Atthill read a paper on the subject before the last meeting of the British Medical Association, and we give his conclusions:

1. Carbolic acid, in the proportion of one part of spirit to two of the acid, is the safest and most generally useful of all the agents employed.

2. Carbolic acid should always be applied by means of a probe, round the point of which a layer of cotton is rolled, the cotton being carried up to the fundus at least twice on each occasion that the applications are made, which should be on every third or fourth day, till marked improvement takes place.

---

*Possibly some texture like goldbeater's skin.

3. Carbolic acid should never be injected into the uterus, except when combined with iodine, in the form known as iodized phenol.

4. In many cases, iodized phenol may with advantage be applied by means of a probe.

5. In cases in which metrorrhagia or profuse menstruation occurs, depending on an unhealthy condition of the intra-uterine mucous membrane, the cavity being dilated and the uterus enlarged, from half a drachm to a drachm of iodized phenol may be injected with great advantage.

6. In cases in which epithelioma attacks the mucous membrane of the cavity, the injection of iodized phenol promises better results than any other treatment.

7. The success likely to follow the injection of iodized phenol renders the dilatation of the uterus, the use of the curette, and the subsequent application of fuming nitric acid, less frequently necessary than has been the case hitherto.

8. The injection of iodized phenol requires to be carried out with so much care, that it should never be injected except by means of a syringe which will not contain more than one drachm.

9. The use of the fuming nitric acid should be limited, as a rule, to those cases in which dilatation has been practiced, and it should always be applied through a tube, inserted into the cervix uteri for the purpose of protecting the sides of that canal from the action of the acid.

10. The pain produced by the application of any medical agent to the intra-uterine cavity, does not bear any relation to the activity of that agent, but is due to one of two causes—either to hyperæsthesia, or to narrowness of the cervical canal, especially of the os internum.

Special Report.

REPORT ON THE USE OF MURIATE OF COCAINE.

BY DUDLEY S. REYNOLDS, M. D.,

Professor of General Pathology and Diseases of the Eye and Ear in the Hospital College of Medicine, Louisville, Ky.

Reported by ALLEN KELCH, M. D.

I received from a friend in Philadelphia, on the 20th of October, two grains of the muriate of cocaine in a letter. This I dissolved in a drachm of water, and instilled it, a drop every five minutes, into the eye of a patient with a large fleshy pterygium. The instillation was begun at 1:10 p. m. Three instillations being made, I found at 1:30 complete anæsthesia of the conjunctiva. Introduction of the speculum produced but slight discomfort. The vessels of the ptergyium had been greatly contracted, so as to diminish the suffusion which had existed before the use of the drug. I dissected up the apex of the growth, and cut it loose with scissors from its point of attachment to the side of the healthy conjunctiva; and turning it back stitched the conjunctiva together with three sutures, subsequently making incisions around the cornea on each side, and then the usual radiating incisions at right angles with these to relieve tension. All this was done without complaint on the part of the patient. He declared he felt the operation, but experienced no pain.

At 4 p. m., on the same day, Miss N., the subject of double convergent squint, was treated to one instillation into each eye. In three minutes anæsthesia was pretty well established. A second instillation was then made into the right eye, and in one minute more the operation of tenotomy was begun. Introduction of the speculum created no pain, though she said it felt uncomfortable. Seizing the conjunctiva with toothed forceps and snipping it with scissors produced no evidences of discomfort or even consciousness of the proceeding on the part of the patient. Raising the tendon with the blunt hook was painful; it was divided, however, as I thought, with less pain than usually attends the proceeding, the operation being completed in seven minutes from the time of the last instillation, and twelve minutes from the time of the first. The conjunctiva of the left eye tested by touch and finding it insensible, the speculum was introduced and the conjunctiva seized and snipped without hemorrhage. On dividing the fascia the patient complained. I applied a sponge to remove a drop or two of blood which flowed, and dropped into the wound about one minim of the solution of cocaine. In three minutes I was able to pass a probe behind the tendon without pain. On making it tense, however, the patient complained; yet the process of dividing the tendon was accomplished with less complaint than was made at the same proceeding in the fellow eye. Upon the whole, I concluded the cocaine had greatly diminished the patient's sufferings, as well as reduced the hemorrhage.

On the 23d of October a gentleman, twenty-six years of age, of full habit, and who had for a long time been the subject of occasional attacks of acute otitis media, came to see me early in the morning. One drop of the solution of cocaine was placed in the ear upon the surfaces of the drum membrane, which had already been observed to be of a straw color and bulging outward. In three minutes he announced abatement of the

pain; in four minutes he expressed himself as feeling more comfortable than he had since midnight, notwithstanding morphine, including one hypodermic injection, had been administered by the family physician in the night. I then touched the bulging membrane with the end of a probe cautiously; it brought forth no response. I then punctured it freely with the lance, allowing four or five minims of straw-colored fluid, slightly tinged with blood, to make its escape. The patient being unable to blow air through the ear, I introduced an Eustachian catheter and blew out a few shreds of lymph along with a little bloody serum. At one o'clock p. m., the patient had suffered no return of the pain. He went home, took twenty grains of quinine, and went to bed. Next morning, he called to say he felt no discomfort from the ear. Examination showed that the incised membrane had united.

November 7, Mr. B. called; he had lost the sight of the left eye thirty years ago from a wound. During the last year he had noticed the sight failing in the right. Inspection showed incipient cataract. As he was now unable to go alone in the streets, it was decided to lacerate the capsule, allowing the lens to imbibe the aqueous humor in order to hasten the maturation of the cataract for extraction. One drop of the cocaine solution was instilled at 9:30 a. m. At 9:34 the speculum was introduced, and finding the cornea anæsthetic, I passed a needle through and lacerated the capsule vertically from the margin of the dilated pupil below to the corresponding point above; withdrawing the needle, about a drop of aqueous humor escaped, and the speculum was immediately removed. When this was done, the patient asked me what I thought about his eye, and on looking around, announced that everything now looked like snow. He was quite surprised to learn that I had operated.

On the 12th of November, at 2:10 p. m., one drop of the cocaine was again instilled; at 2:10½ another, and at 2:15 anæsthesia being established the speculum was introduced; section of the cornea was completed without the patient's knowledge; seizing the iris with forceps and drawing it out through the lips of the wound, the patient exclaimed, "Be careful." I snipped it off, however, without any twitching or manifestation of pain on the patient's part. The lens quickly followed without coaxing. The speculum was then removed, the lids being closed for a few moments. I practiced the usual circular movements over the closed lids in order to press out all remains of the cortex from the peripheral portion of the capsule, and on reopening the lids no difficulty presented itself in removing what appeared to be all the remaining portion of the cortex. At 2:20 the operation had been completed, and the patient declared that the drops instilled had improved his sight, seemingly unaware that he had been operated upon. It may be proper to say that this patient was eighty-five years of age, though a man of robust health, and apparently, not more than sixty.

November 14, came a child, 7 years old, with congenital catarrh in the right eye. One drop was instilled at 10 a. m., at 10:01 another; 10:05 the patient made no objection to the introduction of the speculum. I instantly thrust a needle through the cornea, and lacerated the capsule freely, carrying the needle into the substance of the lens with a rotary motion, after the fashion of drilling. The needle and speculum were both quickly withdrawn, followed by the escape of two or three drops of aqueous humor, but no tears. The child said it didn't hurt, but felt like pulling the eye. No irritation of consequence followed, and the child, who lives sixteen miles in the country, returned home the next day.

At 11 a. m., Mr. G., a plow-grinder, called with a foreign body in the cornea of the right eye, which was now quite sensitive and suffused, the pupil being narrowly contracted, and the patient complaining of circum-orbital pain. Several ineffectual attempts had been made to remove the body.

One drop of the cocaine produced in two minutes relief to the pain; in four minutes the patient opened the eye freely; in five I separated the lids with my thumb and index finger, and with a spear-pointed needle made a triangular incision into the cornea, and turned out of the proper substance, without pain, a large grain of emery. Almost immediately after its removal, however, the patient complaining, I instilled another drop, which gave prompt relief and almost entire disappearance of the suffusion of blood in the conjunctiva. At 11:30 he left the office with dilated pupil and without pain.

November 15. Mrs. McD. has dacryo-cystitis. During the last four days the eye has been tender to the touch about the inner canthus, and as the tears constantly flow over, the patient comes now for relief. She is filled with fear lest some operation of a painful character may become necessary. At 9:40 an instillation was made. At 9:47 patient permits inspection of the eye with pressure on the globe. I now passed the point of a scissors into the inferior punctum, and dividing it freely,

passed a No. 4 Bowman's probe quite into the sac before the patient was aware of the nature of the proceeding. On attempting to enter the nasal duct, she complained, and would have me withdraw the probe, when a considerable quantity of muco-pus escaped from the enlarged punctum. Another drop of the solution was instilled at 10 a. m. The duct had been fully explored, first with a No. 4 Bowman's probe, then with a No. 6, without any sense of pain whatever. On the 16th she returned, and in five minutes after the instillation of a drop of the cocaine permitted me to pass a No. 6 probe without complaint. This was done daily until the 28th without pain, when the patient was discharged cured.

With a view to determine more exactly the extent of the effects of the cocaine, I obtained a fresh supply from Prof. Diehl, the solution being the same strength as that used before, viz., 2 gr. to the drachm of distilled water.

November 17, there came Mr. T. with a colloid cyst in the upper lid near the centre, and about the size of a marrow-fat pea. He had long had this tumor: there was no pain about the eye, but he complained so much when I everted the lid that I instilled a drop of the solution just named, as much to pacify him as to diminish his sensibility to the proceeding. Seven minutes after this instillation he permitted the eversion of the lid without complaint, whereupon I divided the free border of the lid with a Beer's knife, laying open the cyst, and with a David's spoon scraped out all the contents of the sac. He complained a little, said "it didn't hurt much," and I fancied the hemorrhage was less than usual in such operations.

Miss M., æt. 19, the subject of styes, now has one in each upper lid, attended with considerable inflammatory action, and a great deal of pain. She declines to permit surgical interference. Instilling a drop of the cocaine solution into each eye, she was greatly surprised, in five minutes, to find that she could now permit me to press upon the lids and examine the eyes to my satisfaction without creating pain. Unknown to her, I thrust a knife into one of them, and evacuated its contents. She declared it hurt, and would not permit me to open the one on the other eye. The next day, however, she returned, and after another instillation of the cocaine submitted to the opening of the remaining one.

On the same day, Mr. L., a very neurotic subject, suffering with asthenopia, was subjected to an instillation with the view to determine its effects upon the accommodation of the eye. The sense of pain and soreness in the ball disappeared in two minutes after the application: anæsthesia of the cornea and conjunctiva was established three and a half minutes later. After the lapse of five minutes, no perceptible change in the accommodation had occurred, the patient reading without pain, however, for the first time in weeks. In ten minutes the near point had receded, the patient being still able to read. At fifteen minutes, but little change; at eighteen, his hypermetropia, which had been latent at first, now became manifest; at twenty-five minutes, no change. Another instillation was made: thirty minutes, accommodation almost suspended. No longer able to read, saw $\frac{20}{LXX}$. Glasses brought his vision to $\frac{20}{XL}$, which was the best result possible.

On the 18th, he was subjected to the instillation of an 8 gr. solution of hematropia, when with glasses $+ \frac{1}{18}$ he saw $\frac{20}{XX}$.

(*To be continued.*)

Correspondence.

Hermaphroditism in a Hog.

Eds. Med. and Surg. Reporter:—

A friend had a hog that appeared to be of both sexes. I desired to be at the slaughtering, and though denied the privilege, my friend saved all the private organs except the uterus. I have not dissected them, but a mere inspection shows the testicles to be nearly perfect. Attached to them are the ovaries, with fully formed vesicles. The part answerinng for both penis and vagina was attached to pelvis in same manner as is common to the male, but instead of coming forward to the centre of the belly, emerged about three inches lower than is common for the female, and was in length about two and a half inches, very much resembling a wattle that appears in some hogs on the neck.

This hog showed a strong propensity for intercourse, an in its efforts at coitus with female hogs had ejaculations, which would be, of course, backwards. Any one desiring to see the said parts can do so, as I have them in alcohol.

J. D. F. Lever, M. D.

Columbia, Richland county, S. C., December 12, 1884.

Substitute for Sulphate of Quinine.

Eds. Med. and Surg. Reporter:—

In ordinary cases in which sulphate of quinine is indicated, I am in the habit of prescribing, with satisfactory effects, the following combination of sulphate of cinchonidia, sulphate of cin-

chona, and McKesson & Robbins' powdered purified chinoidine, in the following formula:

℞. Sulphate of cinchonidia.
Sulphate of cinchona.
Powd. purified chinoidine. āā grs. xx.
Syrup, q. s.
Mix.

Divide into 20 pills. Dose, 3 pills every 2 or 3 hours as an ordinary tonic and antiperiodic.

As a cheap prescription for chills, I use the following:

℞. Sulphate of cinchonidia,
Sulphate of cinchona,
Powd. purified chinoidine, āā grs. xx.
Powdered aloes, grs. x.
Powdered sulphate of iron, ferri sulph. exs.
Powdered capsicum, āā grs. xx.
Syrup, q. s.
Mix.
Divide into 21 pills.
Sig.—Dose, 3 pills every 3 hours.

These pills I have found to be not only efficacious in arresting the chills, but a most excellent tonic in giving tone to the general system after the chills have been arrested; and for this purpose I required my chill-patients to continue them for a month or six weeks, to prevent a relapse.

A short time ago, I had among my patients a youth of eighteen years, with moderately severe typhoid fever. It lasted its usual period; and it appeared that the following pills assisted nicely in keeping up his strength:

℞. Sulphate of cinchonidia,
Sulphate of cinchona,
Powdered purified chinoidine, āā grs. xx.
Powdered sulphate of iron, exs.
Powdered capsicum, āā grs. xx.
Syrup, q. s.
Mix.
Divide into 60 pills.
Sig.—Dose, 2 pills every 3 hours.

This is a favorite pill with me in typhoid fever, and I have always found sulphate of iron, as above combined, a fine tonic in continued fever, and when I so treat it convalescence is not nearly so protracted.

J. B. Johnson, M. D.
Washington City, D. C.

News and Miscellany.

The Ideal Physician.

Professor Gairdner thus describes him:

1. He must be careful and accurate, and at the same time a keen and quick observer of nature.

2. He must be able to connect his isolated observations of fact by rapid, and at the same time trustworthy, processes of reasoning.

3. He must, in dealing with emergencies, endeavor to have always what the Greeks (and Dr. John Brown after them) called *ἀγχίνοια*—nearness of the *νοῦς*, *i. e.*, presence of mind.

4. He must, as a surgeon or accoucheur, have much deftness of manipulation—manual dexterity, as we call it; or perhaps still better, ambidexterity.

5. He must treasure in his memory, and be constantly increasing from day to day, large stores of various reading in his own and other languages, in order that not only past observations, but also the vast field of scientific progress in its relation to his art may be constantly before him, or at least freely accessible when wanted.

6. He must be able to write, at the very least, in his own language, with vigor, compactness, and lucidity.

7. He must have a soul above mere money-grubbing; must on no account degrade his profession into a trade; but must be, as far as is possible to human nature, the disinterested friend, the companion, the good genius, I had almost said, of all his patients.

8. For this reason, if for no other, he must in every case have in him the distinctive essence of what is called a gentleman; and if his practice is, or is ever to be, among what are called the upper classes, he must be a gentleman, not only in principle but in detail; not necessarily what is vulgarly and falsely often styled a fine gentleman, but a gentleman in outward manner as much as in the inner spirit.

9. He must be a man endowed with a deep sense of moral responsibility, so as to beget confidence and unfailing trust in him on the part of his fellow-men. Responsibility, therefore, to them in the first instance; but underlying that, and sustaining it as surely as the root and the stem sustain the flower—a deeper and more latent responsibility to him who is the source of all good, and, therefore, of all moral principle and moral responsibility whatever.

Syphilis in Russia.

A foreign exchange says:

The extreme prevalence of syphilis amongst the Russian peasantry has long been recognized by the faculty in the dominions of the Czar. It was asserted, a few years ago, by medical authorities practicing east of the Ural mountains, that all the inhabitants of certain Siberian villages were infected; but precise statistics, as far as syphilis alone is concerned, are not to be obtained, the district authorities massing together all cases of venereal disease in their returns of mortality and sickness. Dr. Tchistiakoff, of St. Petersburg, has recently published a valuable work on *Syphilis amongst the Peasantry;* and a contribution by a female practitioner, Dr. Sinaide Elzina, on the spread of syphilis amongst the wives and children of countrymen, appeared during the past spring in the *Vratsch.* Both these writers have personally inspected a large number of peasants. In 1881, Dr. Tchistiakoff inspected 25,050 persons, in thirty-seven villages, in the Government of Pensa, between Moscow and Samara; of these 1,184 were found to be syphilitic; 385 had condylomata; 352 gummata; in 447, the disease was latent. Dr. Elzina made similar researches in the Government of Toula, south of Moscow. Out of 3,316 children, 413 were syphilitic; and out of 2,159 women 314 had syphilis. In some villages from 32 to 52 per cent. were syphilitic. Out of all these peas-

ants found to be diseased, Tchistiakoff did not find one, and Elzina only one, case of primary sore. Notwithstanding this unfortunate condition of affairs, the general health and and strength of the peasants is said to be quite satisfactory.

Russian Universities.

The following are the figures relating to the Russian universities at the beginning of 1884:

1. St. Petersburg, 99 functionaries (of whom 48 were titular professors) and 2,052 students, the expenses amounting to 429,903 roubles.

2. Moscow, 103 functionaries (57 professors), 2,430 students, and 526,724 roubles expense.

3. Kiew, 105 functionaries (46 professors), 1,475 students, and 460,334 roubles.

4. Charcow, 89 functionaries (51 professors), 821 students, and 367,944 roubles.

5. Kasan, 109 functionaries (47 professors), 776 students, and 379,496 roubles.

6. Warsaw, 79 functionaries (45 professors), 1,003 students, and 293,106 roubles.

7. Dorpat, 65 functionaries (42 professors), 1,426 students, and 256,807 roubles.

8. Odessa, 52 functionaries (28 professors), 374 students, and 252,929 roubles.

There are also at the different universities from one to fourteen per cent. of "free auditors" who are aided or supported by bursaries and subventions. The library of the Odessa University is said to contain 92,454 volumes; that of Kasan, 103,170; Charcow, 103,704; Kiew, 145,032; Moscow, 190,440; Dorpat, 218,893, and Warsaw, 363,250.

A Great Catholic University.

The establishment of a great American Catholic university is now an assured fact. Miss Mary Caldwell, of St. Louis, has contributed $300,000 to start the fund for its endowment, and the Plenary Council, which accepted the gift with many thanks, has assurances from other wealthy Catholics in America and Europe that the $3,000,000 requisite for its complete establishment will be forthcoming. The Council appointed a committee, consisting of Archbishops Gibbons, of Baltimore; Corrigan, of New York; Williams, of Boston; Heiss, of Milwaukee; Ryan, of Philadelphia; Spalding, of Peoria, and Bishop Ireland, to have charge of the matter. Four laymen will be associated with them, one of whom will be Reuben Springer, of Cincinnati, and another Eugene Kelly, of New York. The seat of the institution has not yet been chosen, but it will be either New York, Baltimore, or Cincinnati. It is proposed that the scope of the university shall be very broad. The committee will meet very soon to decide upon the site.

Professor Tyndall on the Germ Theory of Disease.

The distribution of prizes to the successful students of the Harris Institute, Preston, was the occasion of an address by Professor Tyndall on three chief principles of modern science. The doctrine of evolution, the principle of the conservation of energy, and the germ theory of epidemic disease, were the important topics on which Professor Tyndall dwelt with all his well-known powers of oratory and exposition. To Professor Tyndall's right to discuss all these principles of science we can make not the least objection, but whether his complete acceptance of the views implied in the germ theory of disease may be regarded as a matter for congratulation or not, is possibly open to doubt. But it is hardly consonant with what is really known on the matter to assert absolutely that the germ theory is proved for all the diseases which the professor passed under review. We need only add that no new light was thrown on the question.

Artificial Impregnation.

This subject has been discussed, and has its advocates among a certain class of people. Some time ago we reported a case wherein a lawsuit was the result. We now note that the *Gazette Hebdomadaire de Médecine et de Chirurgie* reviews at length a new novel with the suggestive title of "Le Faiseur d'Hommes." The romance is nothing more nor less than a plea in favor of artificial impregnation; the *dramatis personæ* are a childless count and countess and a highly scientific physician. A certain abbé is also introduced, in order to fill out the religious side of the picture. Not to enter into the details of the subject, which are better suited for a treatise on gynæcology than for a popular novel, it suffices to say that the experiment is successful, the result being a son, who is afterward known at court as the "child of the syringe." But the most curious reading is the long and abstruse argument against artificial impregnation which the reviewer introduces into his article. We can liken it to nothing but the discourse on the seven deadly sins ascribed by Chaucer to his parson in the "Canterbury Tales." In fact, the writer's view of the subject from a medical standpoint is scarcely less fanciful than the novelist's.

The Admission of Hypothetical Questions to Experts.

In a recent case reported in the Supreme Court of Nebraska, where a physician was sued for negligence in setting a broken arm, and where the trial resulted in a vindication of his treatment of the fracture, there was an interesting argument as to the admission of hypothetical questions. The counsel for the plaintiff asked the following vague question: "A blow breaking the bone of the arm—the ulna—what tendency would that have as to dislocation at the wrist?" This question was excluded by the trial judge, and upon appeal this was held to be right. The court said that it was indefinite, and not confined to conditions like those under which the plaintiff was injured. Hypothetical questions must be so framed as to fairly reflect facts either admitted or proved by other witnesses.

Cheese Poisoning.

At the recent meeting of the Michigan State Board of Health, Dr. Baker continued his reports on this subject. Seven outbreaks within the State had been reported during the year, 190 persons having been affected in all, but none fatally.

The symptoms were very similar in all cases, consisting of pains in the stomach, muscular cramps, coldness of the extremities, and great prostration, with violent retching and purging for several hours. Specimens of the Lowell cheese had an acid reaction, and a peculiar strong odor, believed to be due to caprylic acid or caproïc acid. Examined under a one-tenth inch immersion objective, the cheese was found to contain the mycelium of a mould, and to be swarming with several kinds of bacteria in active movement.

The Powers of Health Boards.

The powers of health boards in cases of infectious diseases are matters of great public importance, and while the courts will sustain such boards in any proper use of discretionary power, if they go outside of the legal limits prescribed, their acts will not receive sanction. In a recent Massachusetts case the health board finding a case of smallpox too sick to be removed, seized the house where the patient was, alleging the right to do so, practically converted it into a hospital for several weeks. This action the court declared to be beyond the statute and unwarranted.

Items.

—English statistics show that about one infant in every thousand is insusceptible to vaccination.

—In the *Brit. Med. Jour.*, November 1, 1884, Dr. Donald Macphail reports an *ascaris lumbricoides* extracted from the umbilicus of a boy.

—The Syrian College, Beyroot, has tendered to Dr. W. P. Manton, of Detroit, the chair of Gynæcology and Obstetrics in the Medical Department of that college.

—Dr. Christopher Columbus Graham, of Louisville, Kentucky, recently celebrated his *hundredth birthday* in the enjoyment of a banquet tendered to him by his neighbors.

—Mr. William McEwan has offered to give $25,000 to the Edinburgh Medical School, provided $50,000 is raised from other sources. The sum of $75,000 is needed to complete and furnish the building.

—W. P. Horton, jr., of Cleveland, O., has inserted a few drops of the four per cent. solution of muriate of cocaine into the cavity of a sensitive tooth, and a few minutes afterward he used the dental engine without pain.

—One result of the sad death of Dr. Rabbette has been the invention of several forms of apparatus for sucking secretions from the tracheal wound. One of the simplest of these is made on the principle of a dry-cup with a rubber ball.

—According to a French authority, we can cure corns by saturating the stockings at the point covering the corns in a solution of phosphorus in olive oil (one part to three hundred); wear them as usual, and in fifteen or twenty days, it is claimed, the corns will have disappeared.

—Dr. Mullenhoff recently observed that in sealing honey-cells bees add formic acid to the honey by thrusting the abdomen, with the sting protruding and a minute drop of poison adhering, into the half-closed cell. The honey taken from sealed cells is said to be much more stable than that taken from unsealed cells, and Dr. Mullenhoff attributed this to a difference in respect to its contents in formic acid, which is known to be a powerful anti-ferment.

—In the *Gazette Hebdomadaire de Médicine et de Chirurgie*, M. Vigier gives the following formula of an ointment for pityriasis versicolor:

℞. Black soap, 100.00 grammes.
Powdered pumice stone, 50.00 "

Black soap; the writer explains, contains a considerable amount of potash; it forms with pumice a mixture having the consistence of simple ointment.

—According to M. Boursier (*Rev. de Thérap. Médico-Chir.*, No. 15, 1884), hydrate of therpylene possesses very marked antiseptic and deodorizing properties, and can be used for dressing wounds and for painting the throat in diphtheria. The vaporized fluid has a smell of turpentine, and is said to be an efficient agent for the disinfection of rooms. It is extracted by distillation from the buds of several sorts of pine.

—In the *Centralblatt für Gynäkologie* (May 3, 1884), Dr. Roth regards globus hystericus as due to a paræsthesia of the sympathetic. And as the pellitory root has been found useful in paralysis of the tongue and pharynx, the author was led to try it in globus. He gives from ten to twenty drops of the tincture of pyrethrum four times a day. He reports six cases in which he employed this remedy with satisfactory results.

—From the *Gazette des Hopitaux* we learn that at a recent meeting of the Surgical Society of St. Petersburg, Dr. Papow communicated the results of his experience with trichlorated phenol as a local application in erysipelas. The author reached the conclusion that the drug arrests the development of, or destroys, the micro-organisms upon which the disease is supposed to depend. He advised its application in a ten per cent. solution, to be brushed over the diseased part and the adjacent skin.

—Dr. R. S. Smith, in a letter to the *British Medical Journal*, cites three cases in which he has made careful observations as to the influence of the iodoform treatment upon the *bacillus tuberculosis*. In every case there were well-marked symptoms of phthisis—copious expectoration, rapid emaciation, and pyrexia, while the physical signs of consolidation were unmistakable. The sputa contained numerous bacilli. Iodoform was administered, in doses of one grain every four hours, and gradually carried up to two, three, and five grains, respectively. As a result of this treatment, the cough and expectoration ceased, there was a notable increase in body weight, and the physical signs were greatly improved. The bacilli, which had been noticed in such numbers at first, gradually disappeared from the sputa, until only a few remained. The writer acknowledges that these were selected cases, but he feels justified, from the evidence obtained, in assuming that iodoform really exercises a germicidal action upon the micro-organisms of tuberculosis.

SUPPURATIVE ARTHRITIS—ITS CONSERVATIVE TREATMENT.*

BY C. B. NANCREDE, M. D.,

Professor of General and Orthopædic Surgery in the Philadelphia Polyclinic; Surgeon to the Episcopal and St. Christopher's Hospitals.

This paper in reality consists of the brief notes of a case of incised wound of the knee-joint, and the elaborate history of a second case of suppurative arthritis of the wrist-joint. For the history of the latter I am indebted to Dr. Ralph W. Seiss, the family attendant of the patient, to whose unremitting and intelligent care a large share of the recovery must be attributed. Instead of dilating upon the indications for treatment in cases of suppurative arthritis, I will simply let the histories of the cases speak for themselves.

On Saturday, March 25, 1882, I was asked to see J. P. R., æt. 28 years, a patient of Dr. T. S. Crowly. The doctor had first seen him on that day, and had at once directed them to send for me, recognizing the exceeding gravity of the case. J. R. had, the previous Thursday afternoon, cut his right knee with the corner of his hatchet, when the limb was strongly flexed, thus rendering the incision into the capsule non-coincident with that through the skin when the joint was in any other position than extreme flexion; in other words, the joint was opened in a so-called valvular manner. Owing to a nick near the corner of the hatchet, the weapon must have incised the capsule fully to the extent of a fourth of an inch. He at once tied a "chew of tobacco" over the wound, and did some light work until the evening, when he rode home. The next day he returned to his work, which happened then to be light, but unfortunately he walked home, about two miles, which caused enough pain and uneasiness in the joint to induce him to stop to rest several times before reaching home. That evening he still persisted in walking around, without experiencing much uneasiness, and, retiring early, was awakened by very severe pain in the joint, which was red and swollen. Chills, high fever, and slight delirium rapidly supervened. When I first saw him, the joint was filled with fluid, and the peri-articular tissues were swollen and reddened. Rest and ice with opiates utterly failed to control the symptoms, so that by Sunday night the patient was very ill, with a manifestly suppurating joint. Some synovia mingled with pus issued from the incision, both with and without pressure. Upon consultation with Prof. Ashhurst, I freely laid open the original wound upon a director, and then made a free incision upon the outer upper side of the patella, thereby giving vent to a quantity of purulent synovia. The patella came into contact with the femoral condyles, so that no extended search was made for the opening in the capsule. A poultice was applied and morphia exhibited. The next morning the joint had again filled up, but on a second visit the discharge had again found vent, allowing the patella to recede to its normal position. The whole lower half of the thigh and the region of the head of the tibia was converted, within a few days, into a series of ab-

*Read before the Philadelphia County Medical Society, November 19, 1884.

scesses more or less intercommunicating. Suffice it to say, that by free counter-openings, drainage-tubes, antiseptic injections, and immobility of the joint secured by splints and suspension from the ceiling, aided by a proper supporting regimen, with free stimulation, quinine, etc., the patient convalesced. Hot douching, massage and passive movement, in a few months brought the knee to a right angle, and now perfect extension and nearly perfect flexion have been attained. The members will see that the patient walks absolutely without any limp, with a freely-moving, normal joint, which never reminds him of previous trouble, except by passing fatigue, although he tells me that he has formed such a habit of "favoring" his knee, as to make him afraid to exert it much, unless he forgets all about it, when he uses it as freely as ever before. Such a result speaks for itself.

In this case there is no reason to doubt, that the immediate application of a compress and bandage in the form of the "chew of tobacco" and the handkerchief excluding the air, the ride home and the night's rest, all favored primary adhesion of the capsular wound. The next day's work, light as it was, with the walk home and the subsequent evening's exercise, doubtless reopened the recently-healed capsule, air was probably pumped in by the movement of the joint, and suppuration ensued. Perfect quiet of the joint from the moment of reception of the wound, its disinfection and antiseptic dressings, aided by cold, would doubtless have obviated all the subsequent danger and suffering.

I shall now read the notes relative to the case of suppurative arthritis of the wrist and inferior radio-ulnar joints, kindly furnished me by Dr. Seiss:

On April 24, 1884, I was called in the case of Mr. W., a large, powerful man, of splendid constitution, and perfect family history; a builder, he had led an active, out-door life, and had been of regular habits up to within a few years, since when he has been drinking somewhat heavily. One week before I saw him, while wrenching the stopper from a bottle, the neck broke, and the keen edge of the larger fragment, in slipping, cut the ulnar side of his right wrist, producing a wound down to the joint capsule, and about an inch in length. After allowing the free venous bleeding to continue some moments, he forcibly strapped the wound with many layers of court-plaster, applied over this a tight bandage, and then soaked the entire dressing with "Turlington's Balsam." To ease the terrible pain he suffered, he says he consumed about a quart of whisky in a single day, and almost as much the succeeding day. He was given calomel and a "fever mixture" by a local practitioner at Atlantic City, N. J., where the accident occurred, and some five days after the receipt of the injury, was removed by his relatives to Philadelphia.

When I saw him, his hand was encased in a clumsy poultice, on removing which I found the wound partly filled by friable granulations. On examination with a probe and my little finger, I conld plainly feel the capsular ligament, which appeared uninjured; the ulnar artery was also found to be intact; the motions of the wrist-joint were still free. His temperature was 103°; his skin clammy and leaking; tongue foul and coated; respiration hurried; pulse rapid and weak; mind clouded, with a marked tendency towards muttering delirium; his urine was found, on examination next day, to be loaded with albumen. The entire hand and lower forearm were covered with a fiery red blush; the hand was much swollen and puffy. I at once enveloped the entire hand and forearm in a dressing of laudanum and water, equal parts, and placed it upon a forearm splint. I put him upon two grains of sulphate of quinine every two hours, night and day, each dose to be followed by a half ounce of whisky in an ounce of milk—which was increased to three ounces of milk as soon as the stomach was found to bear well the first few doses. I also ordered him to be sponged daily with a solution of alum in alcohol and water.

For seven days after the adoption of the above treatment he grew steadily better, with less sweating, a stronger pulse and respiration, a lower temperature, and his mind was clear. On the evening of the seventh day, his temperature rose rapidly to 103°, and continued to rise, with slight morning remissions, until it reached 104⅓° on the evening of the tenth day. I then found a small abscess forming over the first and second metacarpal bones, which I at once opened by a free incision—permitting the escape of about half an ounce of creamy pus. He immediately improved, but shortly after commenced to have marked night-sweats, with great pain in the hand and forearm, requiring the frequent administration of hypodermic injections of morphia sulphate, to secure rest at night. About a week after the formation of the first abscess, I opened another, situated between the thumb and index finger, by a deep incision, giving vent to a thin glairy pus. This, however, produced but a slight remission of the symptoms, and he rapidly fell into a semi-typhoid state. A few days after the opening of

the second abscess, Prof. C. B. Nancrede saw him in consultation with me. The following conditions now obtained: Careful manipulation gave a slight sensation of grating, showing the presence of eroded bone; examination with a probe showed extensive destruction and separation of tissues, the hand being little more than a bag of bones; the wrist-joint was stiff, and gave distinct crepitus on motion. The original wound was covered with exuberant granulations. General conditions markedly septic and typhoid. A counter-opening was now made on the radial side of the wrist, a grooved director being passed through my incision over the second metocarpal, which had been kept freely open, directly through the opening. The pulsation of the bare artery (radial) could be plainly felt under the director. Upon suggestion of Dr. Nancrede, the hand was now enveloped in dressings of hydrarg. bichloride, one part to 2000 of boiled water, and three-drop doses of tincture ferri chloridi were given every two hours, in addition to the treatment already adopted. This caused a slight amelioration in the symptoms. Thorough drainage was maintained by the use of drainage-threads of ligature silk, and all the openings were carefully syringed twice daily with the hydrarg. solution. The quinine and whisky were continued, together with hot broths and concentrated foods of all kinds. His average morning temperature was now 101½°, his evening rise from one degree to two and a quarter degrees; pulse always rapid and feeble—from 98 to 119; respirations hurried, mind clear; took food willingly; had occasional fits of restlessness and pain, requiring hypodermics of morphia; some night-sweats; a trace of albumen constantly found in urine, but no casts could be found at any time. For two weeks this state of things continued, with little change for better or worse. Then commenced a train of markedly septic symptoms; lungs frequently congested; some cough; marked night-sweats; hurried pulse and respiration; furred and heavily-coated tongue; intense pain in hand; urine loaded with albumen; occasional, though rare, chills. Some fourteen days after the first consultation, his temperature began to rise steadily until it reached 105° on the sixteenth day after our first consultation, and he now failed so rapidly that I feared speedy death from exhaustion.

On the evening of the sixteenth day I discovered a deep-seated abscess over the distal ends of the ulna and radius. The same evening I again saw him with Dr. Nancrede, when the following operation was performed: Dr. Nancrede made a free incision over the abscess and dissected down on a director until the joint was reached; the latter was opened, and about a half ounce of pus allowed to escape from it.

On examination with the probe and finger, the articular surfaces of the inferior radio-ulnar joint were found to be deeply eroded. The bones of the proximal row of the carpus and the articular surface of the radius were also found to be softened and partially denuded of cartilage. A director was pushed through the radio-carpal joint until it could be felt under the skin and the dorsal aspect of the wrist, where a free counter-opening was made down upon it. The wound was now thoroughly syringed with the hydrarg. solution and a stream of the latter forced through the radio-carpal joint, moderately forcible extension being made to facilitate the passage of the solution. The hand was now most carefully cleansed with the antiseptic solution and antiseptic irrigation was used, the hand and forearm simply resting on a bed of raw cotton, covered by lint kept constantly soaked with the bichloride solution; the amount of whisky he had been taken steadily since I first saw him was increased, and the dose of quinine raised to twenty-eight grains per diem. The night of the operation he suffered intense pain in the hand, requiring two hypodermic injections of morphia, each of one-fourth grain, to produce quiet.

With the exception of one more small abscess on the dorsal aspect of the hand, which I opened, and its attendant symptoms, and a troublesome pressure-sore on his elbow, he now steadily improved. It having been found absolutely necessary to open the sheath of a tendon—palmaris longis?—in opening the joint, some slight trouble occurred from hernia of the tendon, it occasionally extruding to the extent of nearly two centimetres; it was carefully returned at each of the two daily dressings, and attempts made to keep it in place by a compress lightly applied. It perfectly returned to its normal position as the wound closed. A large amount of bloody synovia could be pressed from the sheath of this tendon at each dressing. In ten days he was able to sit up for a short time, and the doses of both quinine and whisky were now lessened. After some weeks of treatment with the bichloride solution, he exhibited marked mild mercurial poisoning, and carbolic-acid solution, one part pure crystals to forty-five of boiled water, was substituted. In three weeks the arm was put upon a wooden forearm-splint, still enveloped in wet carbolic-acid dressings, and he was able to move about his

room. About a week later he went downstairs for the first time. The quinine and alcohol were now reduced to tonic doses. The wounds were now completely blocked with healthy granulations; and, therefore, the wet carbolic-acid dressings were discontinued, the wounds being dressed with carbolized cosmoline—one to forty pure crystals—and later, with oxide of zinc ointment. Passive motion was now made for some minutes, night and morning. After some three weeks of this treatment, *thirteen weeks* after receiving the injury, he was able to leave the house for a short walk; and *fifteen weeks* after the accident he was able to go about and attend to his affairs almost as usual, wearing his arm on an accurately-moulded splint of binder's board, with the wounds entirely healed.

I now saw him but three or four times weekly, and at each visit thorough friction with alcohol on a handful of raw cotton, thorough massage and passive motion of the entire arm were practiced. The elbow was now exceedingly stiff, the shoulder-joint equally so, the wrist anchylosed, thumb almost rigid, only slight motion of the fingers. The binder's-board splint was now soon abandoned, and he was instructed to make constant efforts to move all the joints of his arm, forearm, and hand. I saw him weekly and made strong passive motion of all the stiffened joints at each visit.

At present, six months after accident, his condition is as follows: Weight, 185 pounds—being a gain of 26 pounds in about nine weeks — general health good; some neuralgic pain in injured hand occasionally; shoulder slightly stiff, deltoid muscle unable to lift it to normal height. Elbow stiff, but hand can be brought directly back to within eight inches of the shoulder—which, the wrist-joint being anchylosed, is almost normal. The forearm cannot be pronated nor supinated, save to a very slight extent. The wrist-joint, as a whole, has a slight degree of extension and flexion. The fingers have more than three-fourths normal flexion and extension, and that quite free. The thumb has its free movements, and is but very slightly stiffened. He writes, with the injured member, a very fair hand, and can continue its efforts long enough to write four pages of "legal cap" without rest. The hand can also be rapidly used for all ordinary purposes not requiring much strength. He feels changes in the weather badly in the entire right arm, but apart from this, the occasional neuralgia and a feeling of weakness and tenderness in the member, uses it as freely as the other uninjured hand.

In conclusion, I would again reiterate that free incision, drainage, and rest, combined with antiseptic treatment in its broadest sense, will, when judiciously followed by persistent passive movement and massage, often save not only life and limb, but an excellent joint, such as I show you in these two cases to-night.

THE LEGAL CONTROL OF MEDICAL PRACTICE BY A STATE EXAMINATION;*

BY JOHN B. ROBERTS, M. D.,

Of Philadelphia,

Professor of Anatomy and Surgery in the Philadelphia Polyclinic.

It is my intention this evening to briefly review the advantages that would accrue to the public and the medical profession by the enactment of a law placing the control of medical practice in the hands of a State Board of Examiners. As is known to many of you, a person who desires to practice medicine in Germany must pass a governmental examination. The students study in universities, and take degrees, but such degrees do not confer the right to enter upon practice. The health and lives of the citizens of the empire are believed too valuable to be imperiled by the acts of ignorant physicians. Hence, although the universities themselves are under the supervision of the State, the candidate for practice must, in addition to his university examination for a degree, pass a governmental examination for license, to follow professional work among the people of his vicinity. He is not a legally qualified practitioner until this is accomplished.

The recklessness with which medical legislation has been neglected in this State will be apparent when I say that the medical schools are under no State or Federal supervision whatever. They have entire control of the time and character of studies required from the intending practitioner, examine him upon the same, and confer the medical degree, which is at once accepted by the authorities as evidence of sufficient knowledge and skill to entitle the possesser to practice medicine, surgery, and obstetrics in the community. Still further, to encourage wholesale and unrestrained manufacture of physicians, the "doctor manufactories" are, I believe, even exempt from taxation.

Until the year 1881 there existed in this Commonwealth no law whatever regulating medical practice. At that time the law to provide for the

*Read before the Medical Jurisprudence Society of Philadelphia.

registration of all practitioners of medicine and surgery was enacted by the General Assembly of Pennsylvania. It effected much good, and was a distinct step forward, though it has, among other minor defects, the weakness that the possession of a genuine diploma is taken as evidence of knowledge.

As long as the medical schools of the United States are dependent for prosperity upon the number of fees received from pupils, and as long as examinations by the faculties who receive these fees are the sole test of skill, a diploma, even from the highest grade institution, carries with it little value as a diagnostic proof of professional learning. The old Latin proverb has it: "Caveat emptor," "Let the buyer beware." I say, "Caveat æger," "Let the sick man beware," if he believes that the fact of graduation from a renowned college confers intelligence and skill. The placard, "No reasonable offer declined," usually tells the buyer that inferior quality of goods is to be expected. Would that many colleges had the honesty to display a similar escutcheon over their portals, reading, "No reasonable ignorance rejected."

The step I advocate to-night is the creation of a Board of Medical Examiners, under State jurisdiction, which shall examine all persons desiring to enter upon practice in this State, after January 1, 1886, without regard to when, where, or how they obtained medical education. If such an examination by non-interested persons shows the proper qualifications, the candidate is to be furnished with a certificate, and is then registered in the Prothonotary's office as heretofore. Let the medical schools teach, examine, and grant degrees as at present; but let no one practice in this State who has not been examined by those who have no interest in passing or rejecting him. In other words, merely substitute for the diploma the certificate of the State Examining Board, as the requisite of registration.

The greatest advantage derived from such a law would be the protection of the public health from ignorant physicians. Bear in mind that I refer now, not to Indian medicine men, negro herb doctors and other charlatans, but to ignorant physicians, graduates of recognized and reputable schools of the United States and other countries; such as are duly armed with beautifully engraved diplomas signed by leaders of the profession, and, therefore, more dangerous to the community than a whole tribe of Indian "pow-wow-ers."

The United States government long ago adopted a similar plan of examining candidates for its army and navy medical services; so that at the present time its soldiers and sailors, even in distant territories and seas, have an average benefit of better educated physicians than citizens of New York, Philadelphia, or Boston. An army or navy surgeon receives his education in any school, but he enters the federal service only after an examination by a board who had nothing to do with teaching him, and who have no pecuniary interest in passing ignorant candidates.

A second advantage of the plan advocated is the improvement in registration that would take place. By the present law, persons who were in continuous practice for ten years prior to its enactment were allowed to register without diploma and without examination. Such persons, if any still reside in the State unregistered, or if any new ones come into the State, would by the new law be required to show their qualifications for practice by examination. This would be a gain, as it would exclude a certain proportion of uneducated persons.

Section 4 of the Registration Law requires persons coming into this State with diplomas from other countries or States, "to lay the same before the faculty of one of the medical colleges or universities of this commonwealth for inspection, and the faculty, being satisfied as to the qualifications of the applicant and the genuineness of the diploma, shall direct the dean of the faculty to endorse the same, after which such person shall be allowed to register." This imposes a considerable amount of work upon the medical schools, who, doubtless, would gladly be excused from this unpaid and uncongenial labor; for to reject the diploma or graduate of a neighboring institution lays the school open to unjust criticism. Moreover, the law does not state that the said colleges should be schools for under-graduates. Some months ago, application was made to me, as Secretary of the Philadelphia Polyclinic and College for Graduates in Medicine, for certification of a man's qualifications for registration under this act. Undoubtedly, post-graduate medical schools were not intended by the law, and I declined to act in the matter. Moreover, there are loop-holes in the Registration Law by which punishment for practicing illegally can be escaped. A notable case occurred, six or seven months ago, in Clearfield county, and is mentioned in an editorial published in the *Polyclinic* for March, 1884.

An exceedingly important result of the establishment of a State Examining Board in Pennsylvania would be the elevation of the standard of

education in the medical colleges of the country. Many citizens and prospective citizens of the Keystone State study in the colleges of New York, Maryland, Ohio, Michigan, and other States. As soon as it is known that no one can practice in this wealthy commonwealth unless he passes the State examination, such persons will study in the highest-grade schools, and in those whose graduates show the smallest percentage of failure before the Pennsylvania Examining Board. Hence if our schools are the best equipped and supply the best education, men will not pay their money to the teachers, boarding-house keepers, and merchants of other states, but will attend our own schools, and thus increase the business prosperity of Pennsylvania. The competition of low-grade colleges, whether in this or neighboring States, would not then tend to paralyze the efforts of institutions of high educational standard. There would be no longer a premium offered for quick graduation after two years' study and a five minutes' oral examination in each of seven branches.

Another indirect advantage would be this: that students could study in several institutions, and thus gain the benefit of hearing the foremost teachers of various schools, instead of being cognizant of the precepts of but one faculty. The former method of study is certainly the most elevating, as it broadens professional knowledge.

The division of labor resulting from examinations being held by a non-teaching board, having committees in different parts of the State, would make it possible to hold written and manipulative, as well as oral examinations, and thus do better justice to candidates than is possible by an oral examination alone. Again, the examinations not being held all at one time of year, would further accommodate intending practitioners and lessen the labor of the examiners. As it is now, the college faculties, with great inconvenience to themselves, and often with injustice to the pupils, hurry through the examinations of several hundred students in a few days. A gengleman, now dead, who was for years a professor in a large medical school, once told me of a case where a man who failed to pass his examination was actually graduated, because of a clerical error that occurred in the hurry of commencement time. Neither of us knew how many people owed their deaths to that accidental physician. Bright men may have been rejected by similar errors made in hasty examinations. The State Board examination would be conducted leisurely, and being partly written, would show by the records whether a man was unjustly rejected. He would also have the right to a public appeal from the report of the Board, which now he has not. The college examination is, as it should be under the present arrangement, the private business of a private corporation, and, therefore, sealed from public inspection.

Another advantage which deserves consideration, is the power of revoking a man's license to practice, which would be possible if a State Examination Board is instituted. His diploma cannot and could not be taken away, but his certificate of knowledge, character, etc., could be cancelled or withdrawn by the Board if he was convicted of criminal malpractice or similar crime.

The last reason for advocating the law is cogent; but to my mind deserves little attention, because it is a selfish one, which should influence us much less than those previously discussed. Such an examination would weed out and keep out of the profession those persons who, though ignorant of medical science, accept professional duties and emoluments, and thus increase the difficulty of an educated physician gaining a livelihood. There are, undoubtedly, too many physicians for the needs of the closely-settled districts. Fewer doctors, and better ones, would be a boon to most sections of the State. The State examination would effect both objects. The legal profession has, I believe, certain restrictions to indiscriminate admission to the bar. Why should not the medical profession have some similar protection?

Dr. Isaac Ashe speaks of districts in Scotland where sixpenny charges are made by physicians, and says he knows of an English town of 50,000 inhabitants, where one shilling charges are made for medical advice. ["Medical Politics," the Carmichael Prize Essay for 1873, p. 33.] He quotes from the *Medical Press and Circular*, of September 11, 1872, p. 216, the following charges adopted by a practitioner of thirty years' experience: "Midwifery, two shillings and sixpence; advice, sixpence; consultations, one shilling." Is there a barrister in England, or an attorney-at-law in Pennsylvania, who accepts such insignificant fees for professional services? Yet the position of the medical profession in Pennsylvania is little better than that mentioned in England. The poor estimate put upon medical service is due to the overcrowded state of the profession, and the inferior quality of much medical work; both of which conditions would steadily decrease after the initiation of a State examination.

That the medical profession desires the adoption of a State Examining Board, may be assumed

from the recent action of the Philadelphia County Medical Society. At a meeting of the present month, in which this and kindred educational topics were fully discussed by college professors and practitioners, both general and special, the following resolutions were offered. After postponement for printing and circulation, they were adopted :

"*Resolved*, That the Philadelphia County Medical Society believes that the status of the medical profession of this State will be elevated by the establishment of a non-teaching Board of Medical Examiners, whose certificate shall be the only one accepted by the prothonotary's office for physicians registering after January, 1886.

"*Resolved*, That the other county Societies of this State be requested to advocate the establishment of such a Board at the next meeting of the State Society, and to discuss the matter, prior to that meeting, with the members of the General Assembly resident in their counties.

"*Resolved*, That the Corresponding Secretary be directed to transmit a copy of these resolutions to the Secretary of each county society, with the request that immediate action be taken, and reported to this society.

"*Resolved*, That a committee be appointed to draft a law creating a State Board of Examiners for the examination of all persons for license to practice medicine, the said law to be presented at the next meeting of the Medical Society of Pennsylvania by the Philadelphia delegates to that meeting."

Having spoken of the advantageous action of a State Examining Board, I must hastily consider the objections that will be raised to its enactment.

It will be said that physicians living outside of this State, but near its border, are often called to attend patients in Pennsylvania. Very well, let them be examined by the Pennsylvania Board, and register in the county in this State nearest their residence. Shall a physician of New Jersey, Maryland, Delaware, New York, or Ohio, practice continuously in Pennsylvania without being subjected to the same examination as residents of this State? Certainly not. Those, however, who come into the State as consultants with duly licensed practitioners of this State should, of course, be excused from the State examination. So should dentists who do not practice medicine, whether residents or non-residents of the State. In the same manner midwives, who attend the very poor in cases of confinement, should be exempt from professional examination, though they undoubtedly should be registered and give some evidence of obstetric knowledge.

A physician changing his residence within the State would merely be required to register in his new locality, but would have to pass no second examination. Nor should those now legally registered and practicing be required to pass the State examination.

It will be urged as an objection that there are physicians who desire to practice special systems of medicine, and that such a State examination would exclude these from practice. Not at all. Let the Board examine all candidates on anatomy, physiology, pathology, hygiene, surgery, obstetrics, chemistry, and materia medica only, omitting theories of medical practice and therapeutics entirely from the schedule.

I have thus advocated, Mr. President and gentlemen, a measure which will, I believe, add to the wealth and prosperity of the State of Pennsylvania, and elevate the profession of medicine; for whatever elevates the latter must increase the former. The wealth of a community is the health and lives of its citizens. Every useful life saved, every illness shortened, adds to the public treasury. The educated physician may do both; the ignorant physician does neither. I pray you to aid in cultivating the one and eradicating the other.

1118 *Arch street.*

DOUBLE INGUINAL HERNIA IN A MALE INFANT THIRTY-EIGHT DAYS OLD—STRANGULATION ON THE LEFT SIDE—HERNIOTOMY.*

BY L. W. STEINBACH, M. D.,

Adjunct Professor of Anatomy and Surgery in the Philadelphia Polyclinic.

The subject of my remarks, a male infant, was born on September 2 of the present year, at the beginning of the ninth month of utero-gestation. During six weeks preceding labor the mother was confined to her bed or room on account of hemorrhages, due to partial placenta prævia. The infant was feeble and bore evidence of premature birth by its general debility, rather than by any specific sign of incomplete development. I estimated its weight at about five pounds. Within two days the child became jaundiced, but his condition otherwise, as well as that of the mother, was sufficiently favorable for me to cease paying regular visits after the tenth day.

On the morning of October 11, the father called and requested me to see the child, because it had

*Read before the Philadelphia County Medical Society, November 19, 1884.

been unusually restless during the night, and because the mother had noticed a swelling in the groin the previous evening.

Thinking that this swelling as described to me by the father might be a rupture, I visited the child without delay, and on rapid inspection found a deeply-jaundiced little patient, not markedly increased in size since birth, with a tumor in each inguinal region, so that the pubic region resembled a mons veneris, with the adipose tissue well developed. As this, however, was not likely to be the case in so poorly-nourished an infant, I continued my examination by manual palpation, and felt on each side a firm swelling, which reached up to the respective external inguinal ring, and extended obliquely downwards and inwards into the scrotum to the extent of more than two inches. The tumors were hard, and only slightly elastic, but in neither one could I locate the testicle or separate it from the rest of the tumor.

It will appear that the diagnosis must have been easily arrived at, because there are but few pathological conditions likely to be found in an infant that would resemble this, other than hernia, or perhaps hydrocele. Yet, fearing to exert pressure upon such tender structures in order to satisfactorily outline the testicles, I entertained some doubt whether I was really dealing with a case of double inguinal hernia, for which there existed the speculative causes of congenital debility, a patulous canal, and above these an impediment to the easy evacuation of the bladder in the existence of phymosis.

I informed the parents that I believed the child to be suffering with a double hernia, and that I would make an attempt to reduce it.

The amount of manipulation which I considered to be safe not having lessened the size of either tumor, and there being no urgent symptoms, I left, with the promise to return towards evening of the same day, with instructions to the mother to note carefully whether the child urinated, or had a fæcal evacuation. At my evening visit, I learned that the child had had no passage since the preceding day, that it passed but a small amount of urine, and was disinclined to nurse. I now renewed my attempts at reduction, and succeeded in returning the protrusion on the right side into the abdominal cavity, the testicle remaining in the scrotum. Only at this juncture did I become positive of my diagnosis. My exertions to reduce the tumor on the left side proved unavailing. In order to ascertain whether I could induce an evacuation of the bowels without endangering the child's condition, I inserted a small cone of soap into the rectum; this met with prompt response from that organ, and together with the soap a small amount of inspissated mucus, intermixed with, or rather discolored by, fæcal matter, was expelled. This convinced me that a constriction existed somewhere in the intestinal tract. Placing a small compress over the right external inguinal ring, and securing it by a bandage, in order, if possible, to prevent a recurrence of hernia on that side by straining in the act of micturition, I left my patient.

In the morning, and again towards evening of the following day, attempts made at taxis were unsuccessful. Constipation, scanty urination, and refusal to take the breast, continued until the third day, when I consulted with Dr. John B. Roberts, who concurrred in the diagnosis of strangulated hernia.

After some manipulation, which somewhat reduced the tumor in size, and seemed to relieve the symptoms, it was agreed to postpone operative procedure until more urgently required. Towards evening of the same day, the vomiting, which had existed before, became more pronounced, and the copiously-emitted substance, in its consistency, color, and odor, resembled fæcal matter.

About noon of October 14, and therefore the fifth day after the symptoms of hernia were first noticed, and when the child was just six weeks old, an anæsthetic (ether) was administered; and the last, but unsuccessful attempt at reduction having been made, I proceeded, with the material aid of Drs. Roberts, O'Hara, and other gentlemen, to perform herniotomy.

Making an extensive incision through the tegumentary structures, and subsequently dividing two additional layers of investment to the hernia, a sac was reached, which was hard to the touch and distended by fluid contents. A puncture of this sac, and evacuation of its sero-sanguinolent contents by means of a hypodermic syringe, caused its partial collapse, and a trial was made to return the protrusion into the abdominal cavity. This attempt proving ineffectual, the hernial sac was incised. This laid open for view a coil of small intestine of a purplish red hue, and below it the testicle and the epididymis. This last peritoneal investment was the tunica vaginalis testis, and consequently formed the true hernial sac.

Even now an obstacle to the retnrn of the intestine presented itself at the constricted neck of the sac. The tender age of the patient and the

delicate and small structures involved, necessitated the employment of the ophthalmic surgeon's canaliculus knife, in place of a Cooper's hernia bistoury, while a small grooved director served the purpose of a hernia director until an incision enlarged the opening to a sufficient extent to permit the insertion of Levis' hernia director. The hernia was of the oblique variety, and after extensive enlargement of the external inguinal ring over Levis' director, the intestine was returned into the abdominal cavity.

The interrupted wire suture was now employed; the first and second stitches, penetrating all structures from without into the abdominal cavity, approximated the edges of the external abdominal ring. A strip of rubber tubing was inserted, to favor drainage. The loss of blood was insignificant in amount. Antiseptic precautions were observed, by using a solution of corrosive sublimate for the hands, sponges, and towels, whilst the instruments were kept immersed in carbolized water. An existing phymosis, which was regarded a factor in the production of the herniæ, was corrected at the same time.

A few hours after the operation, the child had a normal passage; the urine which was voided contained a dark green sediment, which remained as stains on the napkin. The child took the breast readily, and appeared in no way to be disturbed by the operation. Primary union took place throughout the extent of the wound, and the drainage-tube was removed on the third day, after which the small orifice thus left also closed. No symptoms of peritonitis, or inflammation elsewhere, appeared; the pulse was better than before the herniotomy; the excretions continued regular, and everything gave promise of a favorable result, except that the babe did not gain strength, and the jaundice became rather more pronounced. On the fifth day after the operation, the child died, and I have good reason to believe the cause of death lay elsewhere than in the herniæ.

Not the rarity of the affection induces me to present this case to your attention, but rather my belief in the propriety of performing the operation even in so young an infant. I am not conversant with the literature of the subject, and do not know whether a few or many cases are recorded; but my observation of this one case causes me to make the deduction that the operation should be performed unhesitatingly whenever indications for it exist; and I believe that the more rapid reparative process existing in infancy gives an even more favorable prognosis than the same operation performed on the adult.

Hospital Reports.

ON THE TREATMENT OF ERUPTIVE FEVERS.

BY PROFESSOR DUJARDIN-BEAUMETZ,

Hospital St. Antoine, Paris, France.

(*Continued from page* 10.)

This is my mode of procedure: I apply thickly over the face the emplastrum *de vigo cum mercurio*, and over the whole I dust starch powder, and I take care, by new layers of pomade and starch, to fill in all the fissures and broken places which may afterwards appear in this mask. You will in this way succeed when, be it understood, you have applied this protective mask at the very commencement of the eruption, in causing the pustules on the face to abort, save only those around the lips and mouth, where the incessant muscular movements will be likely to cause the mask to break. In certain cases you may employ the ectroctic method of Serres and Velpeau; a method which consists in opening each vesicle and cauterizing it with nitrate of silver. This process, which cannot be applied to confluent eruptions, ought to be reserved for the pustules which develop on certain points, and in particular on the cornea. As you well know, these pustules may, in their ulterior progress, perforate the cornea and destroy the eye. I have myself seen several instances of total blindness, due to the negligence of the attending physician, who did not interfere in time.

On the part of the mucous membranes, your attention ought especially to be directed to the buccal cavity, where the eruption causes profuse salivation and a painful swelling of the isthmus of the fauces; gargles of Vichy water and chlorate of potassium often relieve these symptoms.

The fever has abated, the general symptoms have improved, and we come to the period of suppuration in patients who have not been vaccinated. Then there is reawakening of the fever, and the grave symptoms appear: in particular the swelling of the hands and the feet. It is to this suppurative period that the efforts of therapeutists have especially been directed. It constitutes the most critical stage of the disease, and it is at this period, more than at any other time, that patients succumb.

Earnest endeavors have, above all, been made to avoid the putrid infection which results from incessant contact of the denuded derm with the pus which bathes it on all sides, and various antiseptic preparations have been used. Chauffard thought that he had found in phenic acid an abortive and curative treatment for confluent variola; Guipon, on the same principle, proposed perchloride of iron; and Jenna, of Buenos Ayres, spirits of turpentine. All these medications have been abandoned, and the profession has returned to local treatment, and in particular to baths and lotions of disinfectant substances, which render us great service, and which I earnestly recommend. These baths should be of a temperature of 95° F., and you should add to the water of the bath chloral solutions of thymol or antiseptic vinegar, and in particular that of Pennés.*

*Disinfectant baths and lotions are prepared in numer-

Their duration should be from half to three-quarters of an hour, and you should have care during the bath to give some stimulant, as rum punch.

I have said nothing of cold baths, which have been employed in the treatment of small-pox by Konig, Winternitz, and by Clement, of Lyons. These cold baths have quite another object, that of combating the hyperpyrexia; and although this practice goes back to Rhazes, it does not seem to have commended itself by its results, and for my part I have no experience with it.

To these local measures we must add the use of disinfectant powders, such as compounds of salicylic acid and starch or talc, as employed by Baudon, and painting with tincture of iodine, as practiced by Boinet, Delioux of Savignac, and Pioch. These dressings, joined to the baths and disinfectant lotions, enable you to rid the patient of the sickening odor which he exhales.

But there is a danger still more formidable than that from purulent absorption. I refer to the cardiac complications. Disnos, Huchard, and Bronardel have given us a faithful picture of the variolic endopericarditis and myocarditis, and have indicated the cause of those sudden deaths which in old people attend the stage of suppuration. It is these troubles in the myocardium which explain the feeble pulse and the anæmic delirium which are also noted in this period, symptoms which we need to combat by tonics and stimulants, especially opium and ether.

Our colleague, Du Castel, has shown us the advantages which we may derive from this ether-opium treatment, and I have myself obtained good results from it in the care of small-pox patients in this hospital. You can employ the ether in subcutaneous injections, being careful to insert them as deeply as possible; as for opium, you can give from two to four grains a day in divided doses of the extract. Or, you may adopt the mode of administration recommended by Constantin Paul for the delirium of febrile diseases, and give every hour or two ten drops of laudanum. To these means you should add alcohol in all its forms; also coffee, caffein, the preparations of cinchona, in a word, all the agents of the tonic medication.

The period of desiccation has arrived, and to hasten the falling of the scabs, you should use soap-baths and inunctions with vaseline, that pomade of mineral origin which renders us such service every day.

It is at this period that vast purulent collections form, and your attention should be called to this fact, for these abscesses ought to be opened early. There will also be an indication to endeavor by a substantial dietary regime to repair the profound alterations which the disease has left behind it.

Such are the principal therapeutic rules applicable to the treatment of small-pox, and I pass now to the treatment of scarlet fever.

Scarlatina, unlike variola, has no prophylactic treatment, for nearly all attempts to prevent this disease by inoculation have failed.*

Impotent to combat the invasion of the disease by vaccination, some physicians have pretended to be able to prevent it by prophylactic medication, and taking as their basis this strange notion that since the ingestion of belladonna gives rise to a scarlatinous eruption, it must therefore cure scarlatina, and following in the wake of Hahnemann, they have proclaimed belladonna as both curative and prophylactic. To-day this question is absolutely settled, and all are agreed in regarding this pretension of the specificity of belladonna as illusory.

Moreover, I regard scarlatina as the least contagious of the eruptive fevers (it is so, at any rate, in Paris), and the small number of scarlet fever patients that we receive into our wards have seldom or never given the disease to other patients. You know, moreover, how different is the mortality of scarlet fever according to the country in which it prevails; and while in England epidemics of this disease are characterized by their gravity, in France, and particularly in Paris, this affection is almost always isolated, and is dangerous principally by the complications which may arise during convalescence. I shall then be very brief concerning the therapeutic indications which the question of treatment suggests.

In the period of invasion, which is generally very short, you may employ sudorific ptisans or teas, liquor ammoniæ acetatis, and especially carbonate of ammonia, which has been vaunted by Peart, by Wilkenson, by Strahl, and by Ricken, of Brussels.

During the period of eruption the indication is to diminish the dryness of the skin, and facilitate desquamation by inunctions made with fatty substances. Some, as West, employ lard, others bacon fat. Scoutetten recommends sweet oil. I am in the habit of using vaseline, which does not oxidize or become rancid. You will do well, then, at the period of desquamation, to practice frequent inunctions of vaseline over the whole body, both to hasten the fall of the epidermic scales, and to protect the skin from exterior agents. This state of

---

ous ways. Delioux, of Savignac, employs baths of hypochlorites, which consist of water containing in solution between three and four ounces of hypochlorite of sodium for a full bath, but he prefers tar-water baths (about three gallons of tar-water to a full bath). You make the chloral bath by adding to the water of the bath three ounces of chloral.

The antiseptic vinegar of Pennés is made as follows:

℞.	Acid, salicylic,	3 parts.
	Acetate of aluminum,	3 parts.
	Concentrated tincture of eucalyptus glob.,	10 parts.
	" " of vervain,	90 parts.
	" " of lavender,	10 parts.
	" " of benzoin,	1 part.
	Acetic acid of 8 degrees,	10 parts.

M.

For a full bath add about three ounces of the above solution.—(Pennés' vinaigré antiseptique, Bull. le Ther. t. xcii., p. 426.)

*Inoculation for scarlatina was attempted by Miguel, Mandl, Petit-Radel, and Most. Miguel made use of blood taken from the scarlatinous patches, and he saw produced around the punctures a red circle, which disappeared the seventh day. These subjects of inoculation are rebellious to scarlatina. Leroy, of Etiolles, witnessed the same results after inoculation with blood from a scarlet fever patient. Mandl has advised inoculation with the product of the miliary vesicles which accompany scarlatina. Darwin practiced inoculation with the liquids furnished by the ulcerations of the pharynx. As for Most, he proposes the inoculation of blood taken from swine affected with a sort of quinsy, accompanied by an erysipelatous eruption. (*a*)

(*a*) Miguel d' Amboise, *Bull. de l'Acad. de Med.*, 9th September, 1834. Leroy d' Etiolles. A study of the preventive treatment of scarlatina by belladonna and by inoculation (*Gaz. Hebd.*, 1878), *Sanné. Art. Scarlatina in Dict. Encyclop. des Sc. Med.*

the skin is, as you know, one of the sources of danger during convalescence, by reason of the renal complications which may arise; you ought then to insist upon the greatest precaution during the period of convalescence, and keep the patient for six weeks in his room, and generally one month in bed, and never allow him to go abroad till there shall have been complete renewal of the epidermis. You can aid this process of reparation by warm baths while the epidermis is scaling off.

I shall not speak here of the pharyngeal complications of scarlet fever; you are familiar with the morbid determinations of this disease to the throat, whether it consist in a pultaceous angina or in a veritable diphtheria, according to Archambault's views, who unites scarlatina and diphtheria in the same description; the same treatment is proper for both, and I need not here repeat what I told you when on the subject of diphtheritic sore throat. But there is another complication which ought to occupy us a few minutes. I refer to the nervous manifestations which accompany certain scarlatinous eruptions, and which are tributary to a treatment to which Trousseau has devoted one of the finest passages of his clinical lectures—I refer to the treatment by cold affusions. Recommended by Currie, this method is become to-day classical, and in the practice of certain physicians, particularly the Germans, it is employed indiscriminately in all cases. Here also as in all the applications of the refrigerent method, it is rather against the manifestations on the part of the nervous system than the elevation of temperature that these cold affusions can render service; and you will not need to put this mode of treatment in practice, unless there shall supervene at the commencement of the period of eruption, ataxo-adynamic phenomena of great gravity. For my part I have never found, since I began the practice of medicine, cases of scarlet fever sufficiently grave and menacing to require such treatment. Scarlatinal dropsy does not offer any special therapeutic indication apart from that which I enunciated while on the subject of the treatment of albuminuria; and without dwelling longer on antiseptic medications proposed for scarlet fever, I pass now to the treatment of measles.

This very contagious, but little dangerous malady, unless by the complications which may arise, does not present any very special therapeutic indications, and treatment should be directed rather to the morbid manifestations determined by the disease than to the disease itself. I shall then say very little on this subject, and you will have to apply here only the general hygienic and therapeutic measures proper to all the eruptive fevers, and which consist in warm sudorific ptisans, as well as the greatest care to prevent all exposure to chills, and in attention to the thoracic organs, so that you can interfere in time if any pulmonary complications manifest themselves.

I have now the therapeutic indications, which I desired to give you for the management of the eruptive fevers.

These lectures complete the course on which I had determined; and incomplete as they are, they will furnish you data of a practical kind concerning the principal diseases which, in our country at least, you will be oftenest called upon to treat.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

(*Concluded from page* 15.)

A Case of United Fracture of Both Bones of the Forearm.

Presented by Charles Meigs Wilson, M. D.

This specimen was taken from an arm, amputated about the middle of the humerus. Eight months previously the girl had fallen from a window and sustained an oblique fracture of the ulna and radius—that of the ulna being about an inch and a half, and that of the radius two inches and a half below the elbow joint. The arm was the seat of several large ulcers, and many sinuses were present. The probe detected dead bone. The specimen shows that there has been no attempt at union in the radius, but that the comminuted fragments being attached to periosteum, have not been destroyed. There has been slight union of the ulna. The cartilages have been destroyed. The joint contained pus, and the internal condyle of the humerus showed a carious condition. The patient made an excellent recovery after the operation.

Case of Multiple Ovarian Fibro-cysts with Sub-Peritoneal Fibroids, and General (Tubercular) Peritonitis.

Presented by Dr. H. M. Fisher.

Barbara K., æt. 40, married, born in Germany, was admitted to the Episcopal Hospital early in July. Her father died of a tumor in the axillary region, one sister of paraplegia at the age of 16, and one brother and one sister are still alive and healthy. She married early, and had three children. Of these one lived but one day, one died at the age of 12 of "dropsy," and the third (a boy of 18) is still living. Two weeks after the birth of the last child she was obliged to get up and make severe muscular exertion, actually laboring in the fields. Soon after this she noticed that she was losing blood *per vaginam*, and that she could no longer nurse her child. This bleeding appears to have recurred at intervals of two weeks for a year or more, and often amounted to a positive hemorrhage. Notwithstanding that this was the case, and that she had occasional attacks of severe pain, she continued to work as usual, until three or four years ago. Three years ago she came to this country. At about this time she noticed a lump in her left groin, and from this time her abdomen steadily increased in size, she was seldom entirely free from pain, her appetite failed, and her bowels were habitually constipated.

Status Præsens.—Patient is anæmic, and has a careworn, haggard look. Abdomen much distended. Distance from xiphoid to umbilicus two inches greater than from umbilicus to symphysis. Percussion clear over abdomen anteriorly, dull in flanks, and fluid moves freely with patient's movement. Hepatic dulness begins in third interspace in mammary line, but not apparently increased in width. Examination of heart reveals a faint systolic apex murmur; examination of lungs gives negative result. Much dyspnœa. The dyspnœa becoming urgent, she was (July 14) tapped in the median line, two inches below um-

bilicus, and eight quarts twelve ounces of a straw-colored fluid, rich in albumen, were removed. Immediately after the tapping, an exceedingly hard mass was noticed in the left iliac region, apparently of the size of a turkey's egg. On the 23d she complained of much pain in the left leg, and the tissues were noticed to be œdematous. This œdema was only slightly relieved by several punctures which were then ordered to be made. From this time till her death patient complained much of dyspnœa, hypogastric pain, and obstinate constipation. She was tapped time and again, and on each occasion a large amount of straw-colored fluid was removed. September 21st patient had a sudden attack of severe dyspnœa in the evening, and died in ten minutes. The post mortem examination was made by the resident physician, Dr. J. K. Mitchell, sixteen hours after death, who furnished me with the following notes:

"Drew off fourteen quarts of fluid from the abdominal cavity by trocars and canula, all clear and straw-colored. On reinserting canula, a small quantity of dark-brown fluid, looking like beef tea, came through. The belly-walls were very thin; peritoneum everywhere much inflamed; whole intestinal surfaces and peritoneum covered closely with small whitish or pinkish points of tubercle; glands not very much enlarged, but very hard; omentum as thick as one's hand, and of an almost wooden hardness and stiffness. Liver and kidneys apparently perfectly healthy. Two cysts in the broad ligaments of the uterus, one about the size of a base ball, or a little smaller, the other still smaller. One had been tapped by the canula, the other contained about four ounces of the same brown 'ovarian' fluid. The ovaries, macroscopically, seemed healthy, and the uterus was normal in size and position. The lungs, though much compressed, showed no signs of disease and no adhesions. The heart had also been forced with the lungs upwards; otherwise nothing wrong with it."

A subsequent examination of the specimens brought the following facts to light: The uterus is decidedly hypertrophied, measuring about four inches internally, and appears abnormally hard. Closely attached by false membranes to the lower part of the body of the uterus upon the right side there is a *hard fibrous nodule* of the size of a pigeon's egg. A somewhat *larger mass of similar character* is seen higher up and to the left of the uterus. The right *ovary* is enveloped in false membranes and closely adherent to the fundus of the uterus. The left Fallopian tube opens directly into the larger cyst, of which mention has been made above. This has at its base a fibrous nodule (about $2\frac{1}{2} \times \frac{3}{4}$ inches), which is covered on its under surface by a mass of false membrane. (This is probably the mass that was detected during life in the left inguinal fossa.)

In addition to the cyst above-mentioned there were two other much smaller cysts, but found it impossible to make out the exact relations of these to the other cysts, without making a careful dissection, and this I failed to make. None of these cysts appeared, however, to be connected, as was stated above, with either broad ligament. The left broad ligament was found to be perfectly free; the right was wasting, but appears to have been removed during the autopsy, or subsequently.

The case is a complicated one, but the sequence of pathological events appears to have been the following: The patient having made severe muscular exertion a fortnight after confinement, is attacked by perimetritis and metritis. This inflammation, at first acute, soon becomes chronic in consequence of patient being unable to get proper care and the rest that she required. Whether the subperitoneal fibroids, from which she was found to have suffered, had been already developed at the time this acute pelvic inflammation occurred, it is impossible now to say; but it is probable that they were of later development. Coincident with the periodical hemorrhages and attacks of pain that the patient now suffers from, fresh portions of the pelvic peritoneum are invaded. Finally, the peritoneum adjacent to the ovary is reached, and a perioöphoritis is the result. The inflammation of the peritoneal investment of the ovary extends, as Heitzmann states, to the ovary itself, causing a proliferation of connective tissue in the cortex of the organ, and from here to the adjacent connective tissue stroma. In this way the bursting of a ripened follicle may, as he says, be prevented, and a path may be opened for the formation of an ovarian cyst. Supposing this to have occurred in this particular case, we may easily see how the connective tissue proliferation may have gone on hand in hand, as it were, with the cystic degeneration of the ovary, until the whole ovary was converted into the multiple fibro-cyst that we see in the specimen.

The inflammation extended but slowly from the pelvis to the general peritoneum; probably because the products of inflammation were for a long time, in great measure, circumscribed by false membranes. Little by little, however, these products were taken up by the lymph channels, until finally the whole peritoneal surface was infected by them. The occurrence of general peritonitis probably did not antedate much the occurrence of the abdominal dropsy, three years ago, as before that time the patient, though occasionally incapacitated for work by pain, was still able to attend to her usual occupations during the greater part of the time.

Thursday evening, September 25, 1884. The President, James Tyson, M. D., in the chair.

Dr. Guy Hinsdale exhibited a

Phantom Brain.

The model is constructed in colossal proportions, and is intended to show the course of the fibres in the human brain, and their relation to the several nuclei and the spinal cord. This preparation has been recently purchased for the Mütter Museum of the College of Physicians, and was constructed by Buechi, of Berne, Switzerland, under the supervision of Prof. Aeby.

The height is 125 cm.; its width, 70 cm. The cortex is dotted over with numerous corks 2 cm. long, which are distributed in systematic order. The basal nuclei, of a much larger size, are seen in their appropriate places. The spinal cord, made up of ganglia and columns of wires of different colors, is represented throughout a portion of the cervical region. These columns of the cord, of different colors to distinguish their function, lead to their appropriate ganglia, of corres-

ponding color, or to the areas in the cortex, which are marked by similarly colored corks.

Taking first the anterior and lateral columns of the cord painted red, we can trace these motor fibres to the anterior and lower portion of the medulla, where they decussate, through the pons, to the internal capsule, where, between the caudate nucleus oft he corpus striatum and the optic thalamus, they radiate to the cortex. They are seen to come chiefly from the convolutions about the fissure of Rolando. Where red balls are seen, from that point a red, motor, fibre descends to the anterior or lateral columns. It will be seen that the column of Türck, or direct pyramidal tract, is in relation with the posterior part of the lateral column of the opposite side. As regards the exact localization of the sensory and motor tracts of the spinal cord, there is still some discrepancy of opinion. Prof. Ferrier states that the antero-lateral columns are usually regarded as the chief motor paths, but quotes the recent and careful experiments of Ludwig and Woroschiloff (1874), who place the motor paths in the lateral columns only. The anterior columns (of Türck) are regarded more as commissural connections between the motor nerves and adjacent segments, and not at least the direct paths of motor impulses proceeding from the brain.

Tracing the fibres of the posterior columns, colored blue, we find them represented as wholly decussating in the medulla, forming the posterior third of the internal capsule, and passing to the corpora quadrigemina and optic thalami, colored blue, which are the great centres of sensation.

The external portion of the lateral columns, colored green, are seen to lead to the cerebellum, decussating near its superior surface. The yellow fibres of the model place the basal nuclei in communication with the cortex; the white fibres, constituting the corpus callosum, are purely commissural. The columns of the cord as represented in the model correspond precisely with the arrangement given by Flechsig, and endorsed by Charcot and Hammond. Ludwig and Woroschiloff argue that "a vicarious interchange of function potentially exists between different parts of the cord." Ferrier* admits that in determining the course of the cerebral fibres, anatomy reveals very little, and that physiological experiment is practically the only means at our command. Many more observations and experiments will have to be made before it can be said that the sensory and motor paths have been exactly defined and all views reconciled.

A Case of Infantile Mollities Ossium.

Presented by Dr. Charles Meigs Wilson, for Mr. Clinton Dent, of St. George's Hospital, London.

This specimen was sent to me by Mr. Dent, the well-known editor of the English edition of Billroth's Notes on Clinical Surgery. The following history was also furnished by Mr. Dent:

"This specimen shows the inner vertical half of the right femur of a child æt. 16 months. There is a pseudo-fracture of the bone. The medullary canal is filled up, and a considerable deposit of enveloping callus maintains the fragments in apposition. The entire bone is unnaturally soft, and in the recent state showed this peculiarity still more strongly. The bone was removed *post-mortem* from the body of a feeble, ill-nourished child. No history of syphilis could be gotten from the parents, and the child showed no evidence of congenital syphilis. Some of the ordinary symptoms of rickets were observable, *e. g.*, bending of the ribs, general tenderness, enlargement of the wrists, etc. No symptoms of scurvy were present. It was evident that there was much more than rickets in the condition. When the child was first admitted to the hospital there were pseudo-fractures of the right humerus and left tibia, besides the fracture of the right femur. The humerus, which was bent at a right angle, was forcibly straightened. It bent like a bar of soft metal, and remained in its new position. It was, however, put in a light pasteboard splint, Subsequently, with the removal of the splint, the bone again gradually bent, and was again forcibly straightened. While in the hospital under observation, the femora became affected in the usual place, *i. e.*, a little below the trochanter. Some swelling ond tenderness was noticed, and then, although the child was kept constantly in bed, the bones became bent; ultimately, in about ten days, the pseudo-fractures became complete. Great improvement of general health, as evidenced by rapid increases of weight, resulted from treatment of rest, good diet, and cod-liver oil. The child finally died from an attack of whooping-cough, after having been under observation a few weeks."

This is a very rare form of bone disease, especially in the young. It is seen occasionally in England—never with us. The pathological changes seem to be of a retrograde chararcter. Sometimes lipomatosis takes place. Sometimes there is a metamorphosis first to cartilage and then to embryonic tissue. This specimen shows, in different portions, both changes. The disease is attended with marked fatality. In this specimen the cortical substance is attenuated, and the medullary cavity is enormously enlarged. The bone seems deficient in lime salts. Some authorities believe that the lactic acid found in the chemical analysis of such bones is accountable for this; this fact is mentioned in order to elicit discussion. Other observers have found enormous quantities of oxalate of lime in the urine of patients with malacosteon bones. One curious fact is the effort which nature makes to repair the fractures, as shown in this specimen. This callus seems deficient in inorganic matter, and eventually becomes reabsorbed. Syphilis, scrofula, and scorbutus, have all been assigned as causes of the affection. Most authorities deny the existence of the disease in children, assign it to middle life, and speak of it as being lighted up or aggravated in women by pregnancy.

* Ferrier. Functions of the Brain, p. 5, London, 1876.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, December 4, 1884. The President, R. A. Cleemann, M. D., in the chair.

Ovarian Tumor.

Dr. Drysdale presented a polycystic ovarian tumor which he had removed that morning. He

had first seen the patient with Dr. C. R. Prall, May 5, 1884. She was a married lady, fifty years of age, pale, thin, and delicate-looking. She had had eight children, the youngest of which was then sixteen years old. With some trifling exceptions, her menstruation had been perfectly natural until two months before; since then she had had a constant and, sometimes, profuse discharge of blood from the vagina, which still continued. She first discovered the tumor in March, 1884.

On examination, Dr. Drysdale found a semi-solid, smooth-walled, globular tumor occupying the lower part of the abdomen and reaching nearly to the umbilicus. It was freely movable, did not fluctuate, but was elastic and a little tender to pressure. Vaginal examination revealed a lacerated cervix. The sound entered the uterus two and a half inches, taking a direction to the right of the tumor. On deep pressure, the end of the sound could be felt at the lower part of the right border of the mass. While the sound was in the uterus the tumor could be moved freely without affecting it. Dr. D. diagnosticated a multilocular ovarian tumor.

By the 5th of June, one month later, it reached nearly to the ensiform cartilage. From this time it increased rapidly in size, and when it was removed, filled the abdomen, pressing the lower ribs outwards. It proved to be a multilocular tumor of the left ovary.

His object in bringing it before the Society was to obtain an opinion from the members as to the cause of a phenomenon which was observed in the early stage of the growth. When the patient first noticed the enlargement, she found that when she would be on her right side, the tumor, as if lighter than the surrounding parts, would ascend to the left, and when on her left side, would rise to the right. She informed Dr. Prall of this, and he naturally supposed she was mistaken; but a careful examination of the tumor while she changed her position verified her assertion. As the mass increased in size, this peculiar change of position ceased, and when the abdomen was opened, nothing could be found to account for the singular behavior of the growth.

Dr. Parvin inquired about the length of the pedicle and the weight of the tumor.

Dr. Da Costa has a case under observation in which the condition of great mobility is present.

Dr. Drysdale replied that the pedicle was extremely short. The tumor weighed thirty-five pounds, and was multilocular in character. At the time of its removal he could not determine any fluctuation. Every parovarian cyst is movable in its early stages. He intended to call attention to the peculiar, and to him unaccountable motion of this particular cyst.

Dr. Charles Meigs Wilson presented the histories of three cases in which the hydrochlorate of cocaine had been used, with the hope of obtaining local analgesia, and reported negative results.

Malignant Disease of Ovaries, Cystic.

Dr. D. Longaker exhibited the specimens, with the following history: The subject from whom this specimen was removed was a German woman, 63 years old. She had been married the last twenty-seven years of her life, and was sterile. During the last five months she was under the care of Dr. Joseph S. Gibb, of this city, at whose request I first saw her, and by whose kindness I am enabled to report the case. The menopause was established at fifty-three—ten years ago. The patient had always enjoyed fair health, but four years ago she again began to have a bloody discharge from the vagina. For this she consulted a doctor, and was soon well again. The date of the onset of her last illness was indefinite. It was insidious, and the particular symptom for which she desired relief was inability to micturate; this was found to be due to suppression of the secretion of urine, as the bladder was empty. There was also decided interference with nutrition. Her appetite and strength failed rapidly. The urine was found to contain a very small amount of albumen. She had occasional nausea, and bilious vomiting, and diarrhœa. She suffered with pain in the left side of the abdomen. On examination, the doctor discovered a hard tumor, nodulated, to the left of the uterus, projecting upwards into the left inguinal region. It was adherent, and but slightly movable. She was first seen by me on October 6th. At this time she was in bed, suffered from orthopnœa, and was unable to rest or lie down. Her abdominal cavity was greatly distended by a fluid which had accumulated rapidly in the previous three or four weeks. Œdema of the ankles had been noticed a few days before. Her general appearance was decidedly anæmic and cachectic. The abdomen was very tender to palpation, especially over the left inguinal and hypogastric regions. The flanks were bulging, and were flat on percussion. The tumor could be indistinctly outlined, immobile, lying in contact with the left ilium, dipping down into the true pelvis behind and to the left of the uterus and distinct from it. The cervix had undergone senile absorption, but from the os externum a small polyp was hanging in the vagina. October 7th she was tapped; a large bucketful of a brownish-red fluid, of specific gravity 1020, was removed. On microscopic examination it was found to contain blood and various corpuscles and epithelium. (The ovarian cell was not found.) It contained paralbumen.

A more careful examination now revealed a circumscribed, clearly-defined, firm, nodulated growth in the region already indicated. It was found adherent, and could be only slightly displaced. It was of the size of a large fist. Palliative treatment was continued, but the patient's condition gradually grew worse. There was again a slight accumulation of fluid in the abdominal cavity. She was subject to attacks of bilious vomiting and diarrhœa, alternated with constipation, There was no apparent increase in the size of the tumor, and during this period pain was not a marked symptom. At no time was there acute suffering. She died of exhaustion November 27.

Autopsy on the next day by Dr. Gibb, in the presence of and assisted by Dr. E. W. Holmes and myself. The subcutaneous fat had been almost entirely absorbed. The parietal peritoneum was covered with lymph, with numerous nodular elevations in various stages of organization. The intestines had contracted numerous adhesions.

The capsule of the liver was one-eighth inch thick. In the mesentery there were also deposits of lymph, some of which were more recent and less organized. The abdominal cavity contained about two quarts of fluid, the same as that already described.

On the left side, extending two inches above the pelvic brim, was found a tumor apparently solid, but which on close examination was found to be cystic. One of the largest of the cysts had ruptured; the opening was found at the posterior inferior portion of the growth. It was not recent. The capacity of the emptied cyst was about four ounces. The tumor dipped down into the true pelvis between the broad and the utero-sacral ligaments of the left side. It was very adherent, and was removed with great difficulty. On incising and freely opening the cyst, some coagulated fibrin was found, the remains of a hemorrhage into the cavity. When it was entirely removed, it was found to arise from the left ovary. The oviduct was slightly dilated, and its fimbriated extremity was adherent to and spread out over the tumor.

On the right side, in the broad ligament, there is a cyst slightly larger than the tumor. Its contents are dark and very dense. It is very heavy. The cyst is surrounded by a dilated fallopian tube, containing a clear transparent fluid of a bluish-white hue. At its widest part it is an inch in diameter. Behind and below this cyst is found the right ovary; it is adherent, flattened out, and seems continuous with it. The entire specimen was carefully dissected out as it is shown. From its rapidly fatal tendency, with the macroscopic appearance of the tumor, there is very little doubt that a microscopic examination will reveal it to be malignant. Though perhaps possessing the greater pathological interest, there are also a few points in the case which may concern us in regard to diagnosis and treatment. Study of the fluid at first causes a suspicion that it came from a cyst; its high specific gravity and the chemical tests to which it answered favored such a view. But this was entirely at variance with the history of rapid accumulation and absence of physical signs indicating the existence of a large cyst. It was apparent at the autopsy that an attempt at extirpation could only have hastened the fatal result.

The specimen was referred to a committee for further investigation.

Periscope.

The Administration of Alcohol to Parturient Women.

Dr. Heywood Smith thus writes in the *Medical Press:*

From the time when, through the operation of some inscrutable law, a filiform cell from the male, coming into relation with a simple primitive cell in the female, determines in that cell an elective and developmental energy, differentiated from all other cell-growths in its complexity, so that by multiple fissure and differentiation of tissues it grows into the complete organism of an independent being, until the time when that new being ceases to derive its nourishment from the mother who gave it birth, such mother may, during all that period of eighteen months, be said to be *parturient.*

During this extended period of time she passes through several phases of constitutional energy, which may be divided into conceptive, gestative, parturient, puerperal, and nutritive; to each phase of which life there appertains its own constitutional peculiarity, its physical development, its functional activity, its receptivity of impressions from without, and its behavior under the administration of various foods and drugs.

It will be seen, therefore, that our subject will lead us to the consideration of several different vital conditions, and it will be my object, in as short a time as possible for its due elucidation, to glance at each of these several vital phases, and to see in what way the administration of alcohol acts in each, whether as a help or hindrance to the proper performance of healthy vital activity in the parturient woman.

And first in the conceptive phase. The phenomenon of "blushing," *i. e.*, the reddening of the cheeks, and often the neck and breast in women, is connected more or less with a similar "blushing," if I may so express it, of the ovary. The sexual orgasm is the highest, *i. e.*, the most intense expression of this symptom, wherein the active hyperæmia of the ovary leads, through the exaltation of the energy of the sympathetic system, to a relaxation of the arterioles of the superficies, and produces first a blushing, and then a profuse perspiration. Similarly, though in a minor degree, transient, and, it may be, slight sensations, having relations more or less remote to sexual emotions, calling up the mental impressions of love, shame, or mere embarrassment, are reflected to the skin of the upper region, and the passing wave of maidenly blush is the tell-tale of the mental impression produced.

These transient ovarian blushes, or temporary congestions, when occurring with a frequency that is beyond what may be deemed normal, tend eventually to set up disease in those glands; and we not unfrequently see, where the sexual feelings have been to a certain extent called forth and then repressed, as in an engagement to marry suddenly broken off, that a train of mischief is set up that tends to the development of ovarian tumor. Hence long engagements are physically bad, and breaches of promise fraught with actual harm.

Alcohol administered in sufficient doses relaxes the superficial arterioles, and also, in some way,

whether directly through the brain or reflectively through the sympathetic system, gives increased energy to the organs of reproduction. Hence the misery and crime that so often are the outcome of indulgence in alcoholic beverages, as witnessed by the increase of immorality at seasons of special festivity, a tendency that is too oft set forth in the ribald songs that disgrace such seasons of debauch. The total abstinence from alcohol would, therefore, do more to keep women pure, humanly speaking, than any sort of argument, or bushels of advice.

We now come to the gestative stage, where a woman is bearing about in her body a complex organism, to a certain extent independent of her, and yet, in a way that we scarcely recognize, dependent upon her health and self-control for its growth, development, and even future moral being. How important, therefore, nay, necessary, is it that the parturient woman should keep herself from all impressions from without, and from all morbid suggestions from within that might tend to mar the well-being of the treasured life of which she is the temporary casket. Yet in many cases how great is the temptation, yielded to too often, consequent on the morbid ideas that not unfrequently seem inseparable from the parturient state, to neutralize the depression of spirits by indulgence in alcohol; and the patient, for such she becomes, excuses herself with the idea that she wants *keeping up;* or domestic surroundings, or even the dislike to having many children, so preys on her mind that she flies to alcohol as a fortifier, or to render her perverted imaginations less obnoxious to herself. I once attended a lady, the wife of a member of Parliament, and therefore in a good position, who in several succeeding pregnancies, and, I believe, then only, took to drinking; and so far was she influenced by depression of spirits that she was most importunate, as was also her husband, that abortion should be produced in order to save her from the inordinate craving. Now it is of the greatest importance that the pregnant woman should maintain perfect health, but as the administration of alcohol supplies an extra hydrocarbon for the production of animal heat, either more caloric is produced than is needed, or there is an accumulation of unconsumed hydrocarbons that clog the system as fat, renders the woman less active than she ought to be in that condition, and, it may be, acts on the fœtus deleteriously by disturbing the balance of health in the mother's blood, on which it draws for its ever-increasing growth. A pregnant woman should, therefore, avoid alcohol in order to maintain her digestive function in the state of highest efficiency, considering that she is responsible to her husband, the commonwealth, and her God, to nurture and protect to the utmost of her power the new life that is springing up within her.

Next in order comes the parturient phase. As in the vegetable kingdom there is a period of impregnation, then of growth, and lastly, of maturation and separation from the parent plant, the duration of each stage varying according to its special cycle, each after its kind—so is the fruit-bearing in the animal kingdom. To each order is its own appointed cycle, each after its kind. In the vegetable kingdom there arrives a period of time when degeneration takes place in the connective tissue that binds the woody fibre of the stalk of the ripening fruit to the parent stem, until the time arrives when the force of gravity overcomes the cohesion of the parts, and the apple falls. So in the animal kingdom there comes a time when, the fruit being ripe, a degeneration takes place between the outer layer of the egg and the containing matrix, and the uterus, no longer recognizing the fœtus as an inherent part of its organism, deems it a foreign body, and proceeds to throw it off. The process calls forth considerable muscular and nervous energy, which necessitates the highest functional health of the animal, and it proceeds by rhythmical efforts, accompanied with suffering. Now, alcohol is an anæsthetic, and Dr. Prince, of Jacksonville, Illinois, has recently published some observations on its action during operations, the mode of administration being both by imbibition and by rectal enemata.

The reports of our midwives and others practicing among the poorer classes reveal the sad fact that women not unfrequently during the parturient stage are more or less under the influence of alcohol in some form or other, with the view partly of stimulating the action of the womb, and partly of relieving pain. But that is no reason why the husband and the select circle of assisting (?) female friends should also reduce themselves to a condition of helpless anæsthesia! In common with other anæsthetics, alcohol, when pushed in its administration, causes a relaxation of nervous and muscular energy, and so leads to the possibility—or, rather, probability—of hemorrhage. If, therefore, the parturient woman has good health and sufficient fortitude, it is better for her, in all respects, to abstain from the use of anæsthetics.

Following the parturient effort, we arrive, fourthly, at the puerperal stage. And here, following the advice of officious friends, the patient may be induced to imagine she has need of some "pick-me-up" to sustain her strength, and repair the exhaustion of labor. In such cases the exhibition of alcohol leads to dire results. For, on the completion of labor, there commences the process of involution of the uterus; and this process is carried on by means of fatty degeneration of the contractile tissue of the organ, which is eliminated partly through the secretion of the milk, and partly by the combustion of the fatty elements maintaining the general heat. But the presence of alcohol retards the process, as the hydrocarbon alcohol is more easily burnt off than the fatty hydrocarbons; and the retardation of involution, recognized by us as subinvolution, leads to the permanent enlargement of the uterus, and all the evils that follow in its train, as chronic cervicitis, misplacements, and prolapsus. Aiding this tendency to subinvolution is the want of proper, healthy, tonic contraction of the uterus, inducing in some cases too profuse a sanguinary discharge, and paving the way for the too ready absorption of septic material.

The atony resulting from chronic alcoholism may lead also to passive congestion of various outlying parts, as venous inflammation with white leg, mammary abscess from chill more easily affecting the part having its vascular sys-

tem relaxed and engorged, and to a low type of inflammation affecting the uterus itself. A woman will, therefore, best pass through the puerperal state who abstains wholly from alcohol.

Fifthly, and lastly, we come to the consideration of the nutritive phase of the parturient woman—the period of suckling. And here a popular fallacy has worked untold mischief. Nearly all women believe that they cannot give a full supply of milk unless they imbibe several pints of porter or other alcoholic beverage *per diem*. Some of you may remember a picture of Leech's in *Punch*, illustrating nursery French, where a small boy, asking the maid to bring his mother, who is depicted with her infant, her morning glass of frothing porter, says, "*Apportez ici le porter de mamma, et designez le avec une tête.*"

Now nothing is more untrue nor deleterious than the habit that this fallacy engenders. I have often found—and I speak from experience—that when mothers have been bad nurses, the scanty supply of poor milk could be traced to frequent glasses of sherry or other hurtful alcoholic beverages; and have seen, when all such have been laid aside, that the supply of milk has been improved both in quantity and quality. "A lean cow is a good milker" is an adage the truth of which all farmers can bear witness to; and the same may also, as a rule, be said of women. But the fattening tendency of the chronic imbibition of alcohol militates against the woman being a good nurse; and, moreover, some of the poison, passing rapidly and unchanged through the system, passes into the milk, and so the helpless infant becomes an early toper, and might—who knows?—suck in with its mother's milk an hereditary predisposition for the cup that "mocks" and "takes away the heart."

I trust that I have in this short paper proved that the administration of alcohol to parturient women is an unmitigated evil; that in every stage through which she passes it is fraught with the gravest results, both near and remote; and that he does best for those feeble ones committed to his care (as the weaker vessels) who steadfastly, himself conscientiously convinced of the importance of the subject, sets his face to warn women from the pitfall, at the brink of which they may be standing, and to point their minds to a higher channel for satisfaction, and their bodies to a purer beverage.

I cannot conclude without one further remark: that we must not be narrow-minded, nor be carried away with the idea that because a particular drug is poisonous, it is therefore to be eliminated from our materia medica. With just such a show of unreason should we abrogate the use of opium or blue pill. There are undoubtedly cases that call for alcohol, either in its pure form or wrapped in the tonic properties of some wines (where such can be procured unadulterated), and he would be equally to be blamed if, from a mistaken prejudice, he refused to administer it when the requirements of the case demanded, as he who withheld opium in a case of peritonitis.

He is a wise warrior who in his battle against disease in all its varied forms, knows best how to choose his weapon, and recognizes the opportune moment for using it.

The Preparation of Cocaine.

Dr. A. Castaing thus writes in the *N. Y. Med. Jour.*, December 27, 1884:

Cocaine is undoubtedly the great object of interest of the moment, and there is not a physician of progressive ideas who is not anxious to test the marvelous effects of the new anæsthetic. The drug trade, taken unawares by the sudden and sustained demand for cocaine of the various brands which are guarantees of genuineness, is unable to keep pace with it, and is therefore compelled to offer a substitute in many cases inferior to the article called for by the doctor's prescription. The natural consequence is that the anticipated effect is not produced, and the wished-for and confidently-expected local insensibility is not attained. The practitioner is disappointed at his first experiment, his professional pride receives a shock, and in his mind doubt takes the place of the enthusiasm he was at first inspired with. Yet it would be wrong to cast the blame upon cocaine, for the alkaloid, when real and chemically pure, does truly possess the power of producing local anæsthesia, not only on mucous membranes, but also on the whole surface of the epidermis, and, to a certain depth, beneath it.

Considering the difficulties attendant on obtaining the genuine article, we think we shall do well to make known a way, which repeated trials have shown us to be the most effectual, to extract the alkaloid from the *erythroxylon coca*. Having observed that cocaine is extremely susceptible of change under the influence of acids, we studied how to exhaust the coca leaves without using acidulated liquids, and discovered the following method, by which one grain of cocaine can be extracted from four hundred and eighty grains of leaves. To obtain this result, however, it is requisite that the coca leaves be of good quality—that is, gathered at the right time and place, properly dried (a leaf with brown spots on it, resulting from moisture, has lost all value)—and, above all, not injured by age or by exposure to the air and consequent evaporation.

Modus Operandi.—On one part (by weight) of coca-leaves pour eight parts of boiling water, and let them steep for half an hour in a closed vessel in a water-bath. Pour the whole into a percolator, and, when all the liquid part is strained off, continue the exhaustion of the leaves by pouring on them eight parts of alcohol at 85°. Mix the two liquors and precipitate them by means of acetate of lead, draw off with a syphon, and then add sulphate of sodium to remove the salts of lead. Filter and evaporate at a gentle heat until the liquid has attained the consistence of syrup. Treat the whole with water to separate the resinous part, and then precipitate with carbonate of sodium. The precipitate is then to be exhausted by sulphuric ether, and the ethereal solution, after the ether is distilled, is exposed to the air until every trace of ether has comptetely disappeared. By this means is obtained a crystallized residue of a brownish-yellow and of a disagreeable smell. This is impure cocaine.

The coloring matter is removed by washing once or twice with cold alcohol. The cocaine, thus purified, appears in the form of transparent prisms, without smell, bitter to the taste, soluble

in seven hundred parts of cold water, more soluble in alcohol, and entirely soluble in ether. The solution has an alkaline reaction, and, when applied to the tongue, it imparts a bitter taste, and a certain insensibility, followed by a slight sensation of cold, recalling the effect of ether spray upon the epidermis.

Heated to 208° F., the cocaine becomes liquid, and, under the influence of cold, it becomes a transparent mass, which gradually assumes a crystalline form. If it be exposed to a degree of heat higher than 208° F., cocaine changes its color and decomposes. It is inflammable, and burns with a brilliant flame, leaving an ash behind it. It forms soluble salts with acids (its hydrochlorate is the best) and all these salts are more bitter than the alkaloid. It is a compound of carbon, hydrogen, nitrogen, and oxygen.

The medical profession is well acquainted with the effects of wines, extracts, and infusions of coca. I trust that what I have written above will show clearly how its action varies in accordance with the amount of cocaine contained by the leaves, and that, in order to obtain the true therapeutic effects of coca, it is absolutely necessary that the cocaine be titrated at a fixed dose in all its preparations.

The Usefulness of the Nose in Diagnosis.

The *Jour. Am. Med. Ass.*, December 20, 1884, says: Probably every physician sees times in his examination of patients when he devoutly wishes he had no olfactory nerves, or, since to be deprived of the sense of smell would at the same time also deprive him of the possibility of certain keen enjoyments, he prays for that happy condition of the farmer, who, when asked by a young theologian, if he objected to his saying grace at the table, replied, "Oh, no! say what you have a mind to—you can't turn my stomach." Unpleasant as the possession of a nose often is, there are occasions when its delicate appreciation of odors is fortunate. Nay, furthermore, it seems sometimes serviceable in guiding a physician to a correct diagnosis. All are familiar with the fetor of the air expired in cases of pulmonary gangrene. Likewise, the breath of patients suffering from chronic copper and lead poisoning has a foul, strongly suggestive smell.

A peculiar smell of the breath in other diseases has been repeatedly noted by trustworthy observers. Thus, a urinous odor has been detected in the breath of patients suffering from retention of urea in the system from renal disease. The act of coition is stated by a German, whose name we cannot recall, to impart a very characteristic odor of the breath. It is needless to allude to disordered stomachs and constipated bowels, bronchorrhœa, decayed teeth, nasal catarrh, and numberless other conditions familiar to every physician as productive of a foul breath that often leads to a diagnosis upon the very entrance of a patient into the consulting office.

The fetor of uterine cancer is so proverbial that its very mention seems superfluous. *Apropos* of this offensive smell, Dr. Middleton Goldsmith, of Rutland, Vt., in a contribution to the New York *Medical Record*, November 29, 1884, entitled "Some New Facts and Considerations in the Diagnosis of Cancer of the Stomach and Cancer of the Pancreas," cites a case in which the eructations emitted a fetor identical with that of carcinoma uteri. Gastric symptoms usually met with in cancer of the stomach were not marked, though a pronounced cachexia was present. The autopsy revealed an encephaloid cancer involving almost the entire stomach. Upon being accidentally torn into, the organ emitted an overpowering stench identical with that having distinguished the eructations in life. Dr. Goldsmith says this fetor is not invariably present, but that, when it obtains, it may be regarded as pathognomonic of gastric cancer. The fact is well worth remembering.

Peculiar odors do not proceed exclusively from mucous membranes, the skin sometimes emits an unnatural smell in disease.

A pungent mice-like odor is said to be characteristic of typhus.

A sour smell is sometimes perceived to proceed from persons ill with acute articular rheumatism. We do not recall any reference in medical literature, to a singular odor of the perspiration sometimes encountered in phthisical patients. But we recollect vividly two instances in which we were struck by this peculiarity. The first case was that of a man who had a very extensive consolidation of both apices.

The odor did not impress us specially, until a few minutes afterward upon approaching another patient, already stripped for examination, when the same odor met us, surrounding the man like a cloud. At once, without considering the rashness of the statement, we exclaimed to those about, this is a case of chronic consolidation of the lungs. Luckily the examination sustained the diagnosis. In these instances, the odor could not have been due to the medicines taken, as these were devoid of special scent. Whether there be anything in this or not, peculiar odors associated with some diseases are so well established as to render the nose of the diagnostician anything but superfluous.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. A. P. Meylert, in the third edition of his useful essay on the opium habit (New York, G. P. Putnam's Sons, 1885), asserts that the use of this dangerous drug as a private indulgence is decidedly on the increase in our country. In his hands most of the alleged specifics have not produced good results. His treatment depends on the case and circumstances.

——The relation of micro-organisms to disease is discussed in a paper by Dr. S. Laughton, of Bangor, Maine; his conclusion on their action is as follows:

"It becomes more and more evident that it is not alone the presence of pathogenic bacteria which determines the disease, but also the condition of the

body in which these bacteria, as so many seeds, are planted. Indeed, the question at issue between those who accept the contagiousness of bacillus tuberculosis, represented by Koch in Europe, and those who do not accept it, represented by Formad in this country, may be in a good degree settled by considering the relation of the soil to the seed, as well as of the seed to the soil. Not every soil is suited for the same kind of seed. Again, the same soil may be in a fit condition to receive the seed at one time, and not in condition to receive it at another time."

——We cordially recommend to any physician who contemplates visiting Europe for the first time to obtain from Dr. Edward Borck, of St. Louis, a copy of his pamphlet entitled "Home Again." It contains a number of valuable suggestions for the traveler, and also an interesting account of his visit to Copenhagen as a delegate to the International Medical Congress. It is divided into two parts:

PART I.—*Professional Observations.* Hospitals, International Medical Congress, etc., etc.

PART II.—Sight-seeings and general useful information.

BOOK NOTICES.

A Pharmacopœia for the Treatment of Diseases of the Larynx and Pharynx, and Nasal Passages, with Remarks on the Selection of Remedies and Choice of Instruments, and on the Method of making Local Applications. By G. M. Lefferts, M. D. Second edition. 12mo., pp. 101. Price, $1.00. New York: G. P. Putnam's Sons. 1884.

The scope and contents of this little work are so fully set forth in the title that it is not required that we should do more than state that this edition has been carefully revised, and the recent additions to the medicaments for the larynx and adjacent parts included. It is well arranged and neatly illustrated.

Intestinal Obstructions, their Varieties, Pathology, Diagnosis, and Treatment. By Frederick Treves, F. R. C. S. Illustrated. Small 8vo., pp. 515. H. C. Lea's Son & Co., Philadelphia. 1884.

As a justification for the length of his monograph, the author mentions in the preface that more than two thousand persons die every year in England alone of intestinal obstruction in some of its forms. This is a large figure, and shows at once that not only is the lesion a rather common one, but that surgeons up to the present have not been very successful in combating it. This led the Royal College of Surgeons to propose it for a prize essay in 1883, and the present work is hat prize essay, with additions.

The author treats the subject carefully in twenty-six chapters, explaining the varieties of strangulation, volvulus, intussusception, compression, stricture, and the various accidents of obstruction proper. The treatment he divides into non-operative and operative or surgical. There are also certain special forms of treatment applicable to peculiar varieties, which are described in a separate chapter.

A Manual of Bandaging Adapted for Self-Instruction. By C. Henri Leonard, M. D., etc. Illustrated. Second edition. 8vo., cloth, pp. 159. Price, $1.50. The *Illustrated Medical Journal Co.*, Detroit.

To those whose education in minor surgery has been incomplete this volume will be well worth the price asked for it. The whole subject of bandaging and those akin to it, poulticing, strapping, compresses, immovable apparatus, dressing of wounds, are presented in brief and clear language, and in accordance with the recommendations of the best recent authorities. That the demand has required the preparation of a second edition is a proof of the value of the essay.

A Text-Book of Hygiene: a Comprehensive Treatise on the Principles and Practice of Preventive Medicine from an American Standpoint. By George H. Rohe, M. D., etc. 8vo., pp. 828. Baltimore, Thomas & Evans, 1884.

The subjects discussed by the author of this treatise are air, water, food, soil, sewage, the construction of schools, hospitals, barracks, prisons, etc., marine, military, and industrial hygiene, clothing and bathing, epidemics, the germ theory, antiseptics and disinfectants, the disposal of the dead, quarantine and vital statistics.

This, it will be observed, is a wide field, and it requires judicious compression to say all that ought to be said about them upon the compass which the author has allowed himself. He has confined himself to plain statements of the most salient points. The very elementary tone in which portions are written indicate that he had in view readers devoid of any previous knowledge on the subject.

The make-up of the book is rather poor, both paper and press-work being below the average.

The Basic Pathology and Specific Treatment of Diphtheria, Typhoid, Zymotic, Septic, Scorbutic, and Putrescent Diseases Generally. By George. J. Ziegler, M. D. 12mo., pp. 225. Philadelphia, 1884.

The writer of this volume thinks he has made a most important discovery, to wit, that of the one underlying morbific agent of all the formida-

ble list of diseases which he names on his title page. The fact that he has to bring this to the knowledge of the world in a work published by himself seems to indicate that this alleged discovery is distrusted by the medical world at large.

It would hardly be fair to reveal it in the compass of a book notice, and we prefer sending the anxious inquirer about this startling discovery to the volume itself where he will find it presented with the reasoning and evidence of the author; and also in a peculiar diction which has at any rate the stamp of marked originality.

The Principles and Practice of Gynecology. By Thomas Addis Emmett, M. D., LL. D. Third edition. 8vo., pp. 876, illustrated. Philadelphia, H. C. Lea's Son & Co., 1884.

The rapid advance in the branch of diseases of women is well illustrated by the growth and changes in the three editions of this treatise. It is only five years since the first edition passed through the press, and already the author informs us that nearly every chapter has required not merely revision but rewriting.

Such changes betoken not merely an adding to our previous knowledge. Were this all, it would be a matter of unmixed congratulation. Unfortunately, the truth is far from this. In the last five or six years the gynecological world has come to recognize numerous most disastrous errors of practice in which the mistaken zeal of its votaries had plunged it. To mention one only, the abuse of intra-uterine medication, now generally recognized, ruined hopelessly the lives of thousands of women.

We are glad to add that Dr. Emmett has been a conservative teacher, and has generally warned against the extravagances of his fellow specialists, though he acknowledges that he has not fully lived up to his convictions in this respect.

The author lays especial stress on the varieties of pelvic inflammation, and the reader will find this important topic treated nowhere more fully than in his pages. There are few points, indeed, in the branch which are not discussed at length. The details of cases takes up much room which might, it seems to us, have been advantageously reduced.

A Hand-book of Ophthalmic Science and Practice. By Henry E. Juler, F. R. C. S. Illustrated, 8vo., pp. 467. Philadelphia, H. C. Lea's Son & Co., 1884.

Mr. Juler, is a London ophthalmologist of high standing, and his treatise has met with a favorable reception from the British Press. It is eminently practical in tone, and the style is free from the verbiage with which many specialists surround their teachings. The volume is one which can be read with satisfaction by any educated physician. It is, moreover, admirably illustrated, both with numerous wood-cuts and chromo-lithographic plates. Selections from test types are bound in with the volume, and a well-prepared index and table of contents facilitate reference. The arrangement and scope of the text does not offer any material differences from other works on the branch. The manufacture of the book is uncommonly excellent.

A Text-book of Practical Medicine. By Alfred L. Loomis, M. D., LL. D., with 211 illustrations. New York, Wm. Wood & Co. Pp. 1102.

Dr. Loomis has long been known as an acceptable instructor to a large class of students in the University of the city of New York, and as a practitioner of widely-acknowledged skill, any work from his pen is sure, therefore, to command a large popularity with the profession.

The present volume is in fact a recast of his lectures before his annual classes. It is not, however in the form of lectures, but in that of a didactic treatise. The diseases are classified under the different organs to which they have chief reference, and each disease is considered with reference to its pathology, etiology, symptoms, diagnosis, and treatment. Particular attention is given to the morbid anatomy of lesions. This, in the opinion of the author, deserves a higher place than it receives in many treatises.

Another point which the author makes is that many diseases present in this country peculiar features, and are benefited by modes of treatment not entirely the same as those taught in European authorities. This view is unquestionably correct, and it is one that for many years we have urged in the pages of this journal. After long hesitation, it is now slowly receiving acceptance by the profession, and we shall soon see it adopted generally, and no doubt claimed as a discovery by our New York brethren, after their well-known fashion.

In the matter of treatment, Dr. Loomis is not a very strong believer in drugs. He belongs to the school of those who would do nothing rather than run risks. The lover of new remedies will find scant satisfaction in his pages. Here he will be disappointing to the majority of readers, but they will not have to go far to find plenty of authors who make up for his deficiency in this respect.

The numerous illustrations are chiefly of morbid processes, and are well drawn and original.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

GENERAL CARCINOSIS.

To the New York Pathological Society (October 22, 1884), Dr. John A. Wyeth presented a specimen, accompanied by the following history, furnished by his house-surgeon at the Mount Sinai Hospital:

Franz S——, aged thirty years, a native of Germany, single, and a machinist, was admitted September 10. Last May the patient noticed a swelling at the left side of the umbilicus. It gave him no pain. It gradually increased in size downward and forward until it gave him great inconvenience from its size, weight, and position. During the last four months the patient has lost eighty pounds in weight, has had for some time a cough, with some expectoration, occasionally bloody. Last April the patient had his left testicle removed at the German Hospital, presumably for tubercular disease. Of late the pain in the abdominal tumor has become so severe that it prevents him from sleeping. There was no history of gonorrhœa, chancre, or rheumatism; no œdema. One brother and his mother died of phthisis; a remaining sister has some lung trouble.

On admission, the patient had a large tumor involving the umbilical, left inguinal, and left lumbar regions, extending about two inches to the right of the umbilicus downward almost to the symphysis pubis, and also around to the back. The tumor was painful on pressure. Pressure over the region of the left kidney gave rise to pain also on the under surface of the liver and over the left upper half of the thorax, especially near the sternum. There was some bulging at the upper part of the left side of the chest anteriorly, and the outline of the clavicle was entirely obliterated. The left axillary and supra-clavicular glands were much enlarged. The abdominal tumor had a nodular feel, and a number of small, nodular bodies could be felt near it.

Physical examination of the lungs revealed slight dullness and broncho-vesicular breathing at the right apex anteriorly; marked dullness, diminished voice and breathing; crepitant, subcrepitant, and sonorous rales at the left apex an-

teriorly. There was a resonance between the splenic dullness and the tumor.

The patient had marked laryngitis, loss of voice, and spasmodic cough. There had been no hæmaturia at any time. He was much emaciated, his appetite was poor, temperature 100° F., and he complained of constant pain.

September 16.—Great pain in the left leg and thigh, limb cold and mottled, and foot anæsthetic. No pulsation in the femoral artery. The swelling of the left lower extremity continued to increase, accompanied with pain along the course of the artery, and on September 22 several large blebs were observed near the ankle. The general condition of the patient grew worse, and he died on October 15, with symptoms of pulmouary œdema.

Autopsy.—On opening the abdomen a large tumor was found occupying the left inguinal and lumbar regions, and covered by the adherent mesentery. The abdominal wall was not involved. The tumor was firmly attached to the vertebral column, and to it were attached the descending colon and left kidney. The ureter had been compressed by the tumor and hydro-nephrosis had resulted. The tumor seemed to arise from glands in the lower dorsal and lumbar regions, and had surrounded the aorta and vena cava completely. The vertebral column and inter-vertebral cartilages appeared healthy. The left external iliac artery was flattened and nearly occluded by the tumor, and there was thrombosis of the iliac vein extending down into the left femoral. The mesenteric glands were involved, as also were the glands passing below Poupart's ligament, with the femoral vessels. The anterior mediastinum was occupied by a new growth, which was attached to the sternum, and extended backward about one inch behind the trachea, surrounding it and the great vessels of the neck. The apex of the left lung was pushed to the left by the tumor, and the upper lobe was infiltrated with the new growth. The upper lobe of the left lung also contained numerous cavities, and there was marked bronchitis and laryngitis. The right lung appeared normal. The liver showed numerous broken-down white foci, varying in size from one-fourth to two inches in diameter. The kidneys were congested, the spleen and stomach were normal, and the bladder contained nodules similar to those seen in the liver. The brain was not examined.

The specimen had been examined by the pathologist of the hospital, who pronounced the new growth to be cancerous, probably originating in the lumbar glands, with metastasis into the mediastinum and other organs of the body. The point of interest in the case was the fact that the patient was operated upon for removal of a tumor of the testicle, which was considered to be tubercular in character, and within a few months subsequently a new growth occurred in the line of the lymphatics upon the same side of the body, which growth was carcinomatous, and was followed by malignant growths in the lungs, liver, bladder, and mediastinum. The testicle was removed by his colleague, Dr. Gerster, who had presented it to the society as a tubercular testis, and on examining the records of the German Hospital it was found that the case was recorded there as one of tubercular disease of the testicle.

DISINFECTION.

For a subject that has been discussed as much as has the question of disinfection, we certainly are not very close to accurate knowledge. However, we can do considerable in the way of rendering innocuous germs, vapors, or whatever may be the cause of disease. We have rarely seen better advice on this subject than is contained in the summary of Dr. W. J. Miller's article in the *Practitioner*, October, 1884, which he thus wisely concludes:

1. Considering the strength of a disinfectant, which these experiments show to be necessary, it is very doubtful that any efficient disinfection of a room can be practiced while it is occupied. Nevertheless, it is possible that the presence of a disinfectant, though not in sufficient concentration to kill contagium, may by long continuance of operation weaken it, and if microzymes be the contagium, may so lower their vitality as to impair their power to reproduce their kind. A certain degree of probability is given to this by

Prof. Tyndal's observation of the effect of discontinuous heating in sterilizing putrescible liquids, which led him to conclude that there is a period in the life-history of these minute organisms when they are especially vulnerable. It is therefore in the direction of good, to employ some disinfectant during the progress of the case; and there is none equal, either in efficiency or in simplicity of application, to sulphur. It is exceedingly convenient in practice to use sulphur pastilles, as introduced by Dr. Littlejohn, each of which contains twenty-five grains of sulphur, one or two being used at a time, according to the size of the room. This should be done several times a day.

2. The skin of the patient should be sponged several times a day with diluted acetic acid, by preference with the aromatic. This is especially applicable in scarlet fever, effectively disinfecting the desquamating skin. I only mention the method of inunction to emphatically condemn it. The strength of the solution must be regulated by what is found agreeable to the patient; a 1 to 20 solution of the aromatic acid which has been referred to, is generally not too strong.

3. For the final disinfection of the sick-room nothing equals sulphur. But it must be thoroughly applied. The Dundee sanitary authority uses about three pounds of sulphur to a room about ten feet square, carefully closing all apertures by which the fumes might escape, and leaving the room shut up for about four hours.

4. For disinfection of clothing, etc., the method followed here is exposure to a temperature of about 250° for three hours in a specially constructed chamber, the air being also charged with the fumes of about six pounds of sulphur. It is scarcely possible that any contagium can live through such an ordeal.

5. Excreta of patients are best dealt with by Dr. Dougal's method, namely, mixture with hydrochloric acid diluted to 1 to 20. He has proved that this solution does not injure the metal fittings with which it comes for so short a time in contact. Clothes may also be thoroughly disinfected by this agent, and without injury.

6. For hand disinfection, carbolic solution 1 in 20, acetic acid and sulphurous acid are almost certainly thoroughly effective.

7. The question of disinfectant inhalations for lung disease, especially phthisis, demands a longer consideration than can here be given to it; but when we consider that vaccine which had been exposed for three hours to air saturated with creasote vapor, and similarly for four hours to the vapor of eucalyptol, retained its infectivity unimpaired, that the germs to be acted on are far in the recesses of the air vesicles, and that the inhaled disinfectant can only reach them in very weak dilution, if indeed it reaches them at all, it appears to me, although it is very disappointing to arrive at such a conclusion, difficult to place much confidence in this therapeutical expedient.

Notes and Comments.

The Contagiousness of Typhoid Fever.

The contagiousness of typhoid fever has been maintained by some and denied by others. It seems to be one of the questions about which there is considerable latitude of opinion. Hence it will be interesting to read about the cases that Dr. E. A. Cobleigh, of Athens, Tennessee, reports in the *Cincinnati Medical News*, wherein the evidences of contagiousness are very strong. They deserve the careful attention especially of surgeons in charge of hospitals. He thus reports his cases:

"During the month of May, a young man of this vicinity returned home from a neighboring city, rather indisposed. He was aged about 28 years, deformed from early childhood by anterior spinal curvature to moderate degree—the hunchback condition being attributed to an injury received, when quite young, from a fall—but the curvature not materially increasing for many years. This young man, whom we will call J. C., had been engaged for only a few weeks in business in the city aforesaid, and about ten days or two weeks before his return home, he had assisted in 'laying out' a man who was said to have died of typhoid fever. He went to his mother's home, a couple of miles in the country, and a doctor was called, who stated that he feared J. C. was coming down with typhoid. A couple of days

later, as the first physician was professionally absent, another was called to permanently supersede him, and the new man pronounced the case one of septicæmia from absorption of detritus from spinal caries—the last stage of Pott's disease. Under this treatment, the case went on for about five weeks, with a fatal prognosis from the first.

"About three weeks after J. C. came home, I was called to see Mrs. P. B., a young lady of 23 years, in same house. My patient was anæmic and debilitated from prolonged lactation. Her first child was a neice of J. C., and had been nursing him much of the time during his illness. Her case rapidly developed into an open, well-marked, but mild typhoid fever. J. C. was now very low and unconscious. The two cases moved along for three weeks side by side—mine mild, mostly rational, but profoundly debilitated; the other comatose and condemned. Once I saw J. C. at the urgent request of family, but only as bearing on my own case and not for treatment or criticism. That he had a pure typhoid I was firmly convinced, but this I did not say. Thinking him dying for eighteen hours at one time, all remedies were discontinued, when he unexpectedly opened his eyes and rationally called for something to eat. From this point forward, for thirteen weeks, he hung between life and death, alternately conscious and comatose, and then rallied under the care of his first physician (who had been recalled), and recovered.

"Meantime Mrs. B., who had been slowly but steadily improving for several days, imprudently sat up for a few moments in a very weak state, then lay down, turned on her side, complained of nausea, gasped, and was instantly dead of cardiac paralysis. This occurred at the beginning of the fourth week of her illness. The details of these two cases I give rather in full because of their interesting points, as well as their bearing on the history of the outbreak. The others I shall merely mention in brief. About a week after Mrs. B. died, a younger sister of hers, K. B., living in the same house, came down of the disease, and had a mild and brief attack, out of which, however, she came very markedly emaciated. A younger brother of J. C., residing in Iowa, and an older brother, whose home was about one and half miles from the infected house on another road, went to him soon after he fell ill, and were in or about his room most all of the time. The older brother had a very delicate wife and child, both of whom visited J. C. during his confinement, and these two suffered, I am told, from attacks of the same fever. Two other children of this family escaped, these two being stout and healthy.

"The husband of Mrs. P. B. did much nursing of the sick parties, but he had experienced a severe and prolonged typhoid in another State a few years previously, and escaped this time. The younger brother of J. C., from Iowa, came down soon after K. B., and had a long, tedious attack. The older brother escaped. Whether he was protected by a previous occurrence, I am not aware. An older sister, the mother of Mrs. J. B. and K. B., also escaped. This lady was well along in years. Another one of these girls, and in age between the two previously mentioned—also residing in the infected house—came down last of all, but had a very light attack.

"Another, and younger sister of J. C., residing two and a half or three miles distant, came with her husband to nurse the sick, and stayed much in this house. The husband was an old and experienced nurse in typhoid, and escaped. His wife, suckling an infant, fell ill after returning home, and was seriously sick for some time. The nearest neighbor of this family, a mile farther out on the same road, next had a half-grown boy attacked, probably from contagion by intercourse between the two houses, and lastly an invalid brother-in-law of this lad, residing in town, had an attack. No epidemic of typhoid was prevailing in our section at the time these cases occurred, and indeed this fever is rare here—only appearing at rather long intervals. Seven miles southwest of our town, a few imported cases were reported in a neighboring village. With the exception of these, I do not know of any other cases having been heard of in the country, and surely it seems to me that the history of those given shows a pretty good indication of gradual spread by direct contagion. Some years ago a similar outbreak occurred in the town itself, about a dozen cases all told—the first, a young lady just home from boarding-school in Pennsylvania, fatal; the others confined to about three houses, and all directly traceable to apparent infection by personal intercourse with the sick."

Cocaine in Dysphagia.

The following striking example of the successful use of cocaine in overcoming painful deglutition was related by Dr. Jelinek in a paper read before the Vienna Society of Physicians, which has been published in full in the *Wiener Medicinische Wochenschrift* (No. 46):

The patient, a male aged forty-five, was suffering from tubercle. There was extensive swelling, and brawny infiltration of the epiglottis, but only moderate dullness and slight crepitation were discoverable at the apex of the right lung. He had been treated as an out-patient in the clinic of laryngology for three months, and iodoform and morphia had been daily blown into his larynx, and he had constantly taken ice. In spite of this treatment he affirmed that for close upon two months he had only been able to swallow milk in the minutest quantities. He was extremely wasted, incapable of work, scarcely able even to walk, and tortured by continuous pain and thirst. Before applying the cocaine solution Dr. Jelinek made him drink some water. He had hardly swallowed a drop before he started up in the greatest pain, while the water returned through his mouth and nose. Dr. Jelinek then carefully painted the lingual and part of the laryngeal surface of the epiglottis, and the valleculæ, with a ten per cent. solution of cocaine, and a minute afterwards told the patient to drink again. The man anxiously took a small mouthful, for a moment looked around in astonishment, and then, to the surprise of all, greedily swallowed the whole glassful at a single draught. Tears of gratitude filled his eyes, and he could scarcely find words to express his thanks. The next day he related that on reaching home, an hour after the application, he had, to the astonishment of his wife, made an excellent meal (the first he had had for two months) without any difficulty, but that soon after the pain reappeared, and three hours after the painting, was as bad as ever.

Echinococcus of the Neck.

Dr. Lindpainter, of Munich, reports a case of the above in the late *Festschrift des Arztlichen Verein* (*The Medical Press*). The patient had noticed an enlargement of the neck, principally on the left side, from his earliest youth. About ten years ago, after forced yawning, it increased rapidly in size, so that a considerable tumor developed behind the sterno-cleido-mastoid muscle, which caused difficulty of breathing, and was diagnosticated by various physicians as struma. On August 20, 1882, Dr. Lindpainter was called to perform the operation of tracheotomy on account of the difficulty in breathing. He found on the left side of the neck a tumor the size of a man's fist, reaching from the clavicle to the ear. The trachea was forced over to the right, and flexed, so that respiration was exceedingly difficult, and the œsophagus was also so much compressed that fluids even could only be swallowed with difficulty. Dr. Lindpainter took the tumor for a solid struma, calling for tracheotomy, but upon examining more closely he discovered in a small spot above the clavicle distinct fluctuation. After puncture and the evacuation of about three ccm. of clear watery fluid, fluctuation was noted in another part; he punctured this also, and let out about 5 ccm. of similar fluid, after which the trachea straightened itself, and the breathing at once became easy. Examination of the escaped fluid showed the presence of hooklets, and the only further question was the extirpation of the echinococcus. He determined upon incision and drainage. He accordingly incised and inserted a drain on September 2, and in the beginning of December, as no more cysts by that time appeared, the drainage-tube was removed, and in a day or two the wound healed, and at the date of the report, the neck appeared quite well.

Cocaine in Neuralgia.

Dr. William Murrell thus writes in the *British Medical Journal*, December 13, 1884:

During the last three weeks I have used cocaine in six cases of supra-orbital neuralgia, with an account of success which I think justifies a further trial of this mode of treatment. I commenced by rubbing in a four per cent. acqueous solution of hydrochlorate of cocaine, but no beneficial effect was produced, and it was clear that absorption did not take place. I next tried hypodermic injection over the painful spot, of first an eighth, then a quarter, and finally half a grain of the same solution. The relief was almost instantaneous, and lasted from twelve to twenty-four hours, according to the dose employed; but the objection to this mode of treatment is the pain caused by the introduction of even a clean sharp needle. I abandoned this plan, and tried the inunction of first a ten and then a twenty per cent. solution in chloroform. This gave fairly good results, but the chloroform evaporates so quickly as to leave much of the salt on the skin. A better solvent is oil of cloves, and I now use a twenty per cent. solution of the hydrochlorate in that menstruum. I rub in from five to ten minims with the finger, and find that almost instant relief is afforded. We hear a great deal of the toxic action of the drug, but I have never met with bad symptoms of any kind. The real objection to the treatment is the expense, a hundred minims of the twenty per cent. solution costing about £2

10s. In hospital practice it will be found cheaper to employ percussion, which sometimes gives excellent results, or to use a pigment made by rubbing up together equal parts of chloral, menthol, thymol, and camphor.

The Diagnosis of Gastric Disease.

In the *Lancet*, December 13, 1884, we read that methods have been adopted from time to time with a view of determining the digestive activity of the gastric juice outside the body. Van der Velden elaborated a method for carrying out this plan by getting patients to swallow a dry sponge enveloped in a gelatinized capsule. Leube used to wash out the stomach with about 300 cubic centimetres of iced water. Recently M. Beaumetz has adopted the principle of aspiration in order to obtain some gastric juice. There appears to be no need for the practical physician to acquaint himself with the details of the procedure nor with the minutiæ of the apparatus concerned. Van der Velden said that in cancer of the stomach the secretion from this organ contained no hydrochloric acid, and thus believed that an easy way was open for us to distinguish between cancer and other chronic gastric disorders. Leube concluded that the degree of acidity of the gastric juice would give us some idea of the degree of the dyspepsia, and he drew no other conclusion from his careful study of the subject. A certain coloring matter derived from coal-tar, and known as orange-poirier No. 4, or tropeoline, undergoes a change to a clear violet-red tint, when a one per cent. solution is brought in contact with muriatic acid, whilst it does not lose the yellow tint with lactic and other acids. This tropeoline has been employed in testing the condition of the gastric juice. The above information is interesting, but as yet cannot be said to possess any value for clinical medicine.

Operations on Aged Persons.

Since we have already had something to say on this subject, we report with pleasure the following case, which Dr. G. Parker May reports in the *Brit. Med. Jour.*, December 13, 1884:

Mrs. B., aged 84, was long the subject of umbilical hernia. Great corpulency and a chronic cough rendered a truss of little use. On June 5, 1830, strangulation took place, succeeded shortly by fæcal vomiting, resisting the taxis, aided by refrigerating applications and tobacco-enemata. The warm bath was not employed, on account of the great age and helplessness of the patient. An operation was performed at 5 p. m. A mass of omentum was strongly adherent, behind which was a knuckle of intestine, of a dark chocolate color, about five inches in length, which was returned. The omentum, being healthy, was suffered to remain. The bowels acted spontaneously five hours afterwards, and vomiting ceased. Some amount of irritative fever lasted about a fortnight, associated with loss of appetite. Under the administration of cordials, etc., she gradually regained strength, and was restored to her usual condition of health. It is remarkable that about twelve months afterwards strangulation occurred a second time, necessitating another operation. About two feet of bowel appeared below the stricture, which was with difficulty returned, owing to the severe habitual cough to which the patient was subject. She was then in her eighty-sixth year. She did well, and lived more than two years after this operation.

Danger of Too Early Repetition of Iodine Injections in Hydrocele.

Professor Tillaux drew the attention of his class, at the Beaujon, to the danger of being in too great a hurry in repeating injections of iodine in hydrocele. It is only at the end of six weeks or two months that we can judge of the result of the first injection, and to interfere before this time is to expose oneself to induce the formation in the tunica vaginalis of those false membranes which are so vascular that they bleed on the slightest shock, and thus give rise to hæmatocele and the loss of the testicle.

Special Report.

REPORT ON THE USE OF MURIATE OF COCAINE.

BY DUDLEY S. REYNOLDS, M. D.,

Professor of General Pathology and Diseases of the Eye and Ear in the Hospital College of Medicine, Louisville, Ky.

Reported by ALLEN KELCH, M. D.

(*Concluded from page* 29.)

November 19. J. S., æt. 14, suffering with asthenopia, had one drop of the solution instilled at 11:04, 11:04½, 11:05, 11:05½, and 11:06. At 11:20, the accommodation seemed but little disturbed, the pupils being widely dilated. 11:30, accommodation still undisturbed; anæsthesia of the cornea had almost disappeared, and the patient was quite sensitive. One hour later, the pupils were reduced somewhat in size, the eyes which before had felt painful and sore now were

quite comfortable; instillations of the hydrobromate of homatropia were resorted to, and the accommodation being fully suspended, it was found the patient had hyperopic astigmatism equal to $\frac{1}{48}$.

A number of other experiments to determine the effect of the drug upon the accommodative function of the eye yielded variable results; in no case, however, was the accommodation fully suspended by it.

November 22. Mrs. M. H., seventy-two years of age, senile cataract in both eyes. The right eye having failed first, was selected for operation. At 1:20 p. m., a drop of cocaine was instilled; at 1:21, another. At 1:25 the cornea was anæsthetic, and the speculum was introduced. Extraction of the cataract with iridectomy was done without any complaint whatever from the patient.

At 1:45, Mrs. B., æt. 56, with senile cataract in the left eye, was subjected to an instillation of the cocaine. At 1:46, a second. At 1:50 she tolerated the speculum, whereupon the cataract was extracted without iridectomy. The patient said she felt as if the eye were pressed upon. At 2 p. m. she said it felt a little sore, and she had a slight cramping sensation in the lids; no other expression of discomfort was made.

November 26. Miss C., æt. 33, has dense cicatricial opacity of the left cornea; she called to have it tattooed. Explaining to her the unsatisfactory results of that operation, and the possibility of improvement from a somewhat similar proceeding without the use of the pigment, viz., acupuncture, and obtaining her consent, I instilled, at 10:35, one drop of the solution, and at 10:40 I separated the lids with my thumb and index finger and began the process of acupuncture with a spear-pointed needle, which I carried on to my entire satisfaction, without any complaint whatever from the patient, and without the usual flow of tears. On releasing the eye, no suffusion existed; in fact, not the slightest evidence of pain or irritation was present, and the patient left the office with expressions of great satisfaction.

On the same day, Mr. M. brought his son, a boy 7 years old, who had been conducting some experiments with gun-powder, and had three large grains blown into the corneal epithelium. The eye was quite irritable, morbidly sensitive to light, and the boy would not tolerate inspection. The instillation of the cocaine was followed in five minutes by such complete abatement of all sensibility in the eye as to permit an easy inspection of the organ; in two minutes more he permitted me to press the lids widely apart with my fingers, and begin the work of removing the powder. To my astonishment he offered no objection, and the operation was completed without pain.

December 1, Mr. D., a machinist, had a small fragment of brass driven into the cornea three days ago. All attempts at removal had served to increase his sufferings. The eye had been poulticed. He now has violent keratitis. An instillation of a drop of the solution of cocaine into the inner canthus—it being impossible to separate the lids—was made at 9 a. m. At 9:03 he permitted the upper lid to be raised, when another drop was instilled, this time upon the surface of the cornea. At 9:05 his eye was opened, and he said it felt easy. At 9:07 he permitted me to press the lids open, and remove the piece of brass, which was done by an incision by the side of the foreign body with a spear-pointed needle, after which the point was turned in under it, and it was lifted out. Another instillation was then made, and the eye closed with some absorbent cotton and a strip of adhesive plasrer drawn from the cheek to the forehead. The patient returned at 1 p. m., to say the pain was returning, whereupon the dressing was removed, another drop instilled, and he was allowed to go home with his eye uncovered. It is proper to state that the foreign body in this case was about one-half the size of an ordinary pin-head. There was no further return of the pain, and the eye speedily recovered, the pupil being still dilated on the following day.

December 2, 1:15 p. m. Mrs. McH., 77 years old, had a cataract extracted from the right eye the first week in September. Has now an opaque capsule, an instillation of cocaine permitted capsulotomy four minutes later without pain.

Miss Curry. Iritis, excessive lachrymation. December 6, 11:25 a. m., instilled one drop; 11:25½, another drop; 11:27 patient opened eye before the open window; 11:27½, vascular injection perceptibly reduced; 11:28, patient exclaimed, with eyes opened full before the light, "It feels very good;"* 11:29, sat up erect, opened eyes, and with smiling countenance began to tell how difficult was her passage through the street to the office. 11:31 the vascular zone was so reduced as to show only the individual vessels in the limbus. At once the inferior canaliculus was explored into the tear-sac, with a Bowman probe No. 1. Patient did not wince, and denied pain. Withdrawing the probe, patient said, "I'm very much im-

*11:28½ overflow of tears ceased.

proved." She went out of the office with eyes wide open, uncovered, free from overflow of tears, exclaiming, "I am well, almost."

December 4. Mrs. Dr. Grady, of Columbia, Ky., had inferior extraction of cataract from the left eye early in September last. The dressing was worn eleven days; on removing it the eye was painful, red, flooded with tears, and extremely sensitive to light. This continued more or less until now. She is 36 years of age. Has had chronic intermittent fever, is much reduced in flesh, and very nervous, starting at the least sound, and shrinking from the slightest touch. Eye cannot be examined. At 11:53¼ a. m., one drop was introduced at the inner canthus, it being impossible to expose the ball; at 11:53¾ another drop was introduced, followed by a gush of tears; at 11:55 another drop, this on the cornea; 11:56 vascularity of conjunctiva diminished; 11:57 overflow of tears ceased; 11:58¼ insensibility of cornea to touch. She said, "It don't hurt. I don't feel it, but I don't like to think you are going to touch it." Inspection now showed occlusion of pupil, a band of connective tissue extending vertically through the iris. The iris bulged on both sides of this central line, quite into contact with the cornea, several large vessels passing through the line of cicatrization of the cornea into the connective tissue, which binds iris to lens capsule. Considerable cyclitis. At 12 the husband made the first entirely satisfactory examination since the operation in September. In reply to question, she said she felt no pain from the separation of the lids, pressure upon the globe, nor from muscular movement. 12:05¼, complete muscular control with lid voluntarily opened; 12:07½, slight evidence of returning sensibility to touch; 12:11½ she went to the glass to look at her own eye, which was now freely open. She exclaimed, "It looks awful without a pupil." 12:18, eye felt as if sand were in it, and she was anxious to go to the infirmary before full return of pain and sensibility to light.

(Notes taken and time kept by Mr. William J. Evans.)

December 5. Mrs. R., epithelioma of the lower lid, extending from the outer canthus about one-fourth inch along the free border of the lid, and occupying the palpebral conjunctiva quite back to the retrotarsal fold. Instillation of cocaine at 3:10 p. m. and 3:11. At 3:18, patient permitted section of the outer canthus. Being asked if it hurt much, she answered in the affirmative, though she had not cried out. While she was talking about it, the skin was divided near the lash with a Beer's knife, when the scissors was made then to grasp the cartilage, dividing it freely, and the retrotarsal conjunctiva being next divided, the cartilage, with the cancerous mass detached, was lifted out. The patient, though nervous and sensitive to the slightest touch on first examination, permitted all this without wincing, yet she said it hurt.

It is apparent that the cocaine does not permit entirely painless tenotomy in squint; that abscesses, cystic tumors, and epithelioma of the lid may all be operated upon with but very slight pain; that pterygium, foreign bodies in the cornea, iridectomy, capsulotomy, acupuncture, and other similar operations, may all be done absolutely without pain. Amongst the more painful manipulations in ophthalmic surgery are those attending the treatment of diseases of the lachrymal passages. These may be all done now without pain under the influence of cocaine. The best form for administration, in my judgment, is a solution of two grains of the salt to one drachm of distilled water. One drop placed upon the cornea is amply sufficient to produce complete anæsthesia in about five minutes. Two drops at intervals of one-half minute or a minute will produce as profound anæsthesia as may be desired for any operation upon the ball.

For tenotomy, it is but to instill a drop into the wound before dividing the tendon; decided effects follow the instillation inside of two minutes.

It will relieve the pain of iritis as promptly as will any other drug. It seems alike analgesic and anæsthetic. The first specimens used were made by Merck, of Darmstadt. It is now made of very superior quality in this country, by McKesson & Robbins, of New York.

Correspondence.

Salisbury Steak and Treatment.

Eds. Med. and Surg. Reporter:—

Requests have come to me from different physicians asking me to explain more fully about the "Salisbury steak and treatment." It will save me time and writing if you will kindly publish the following in the Med. and Surg. Reporter:

The Salisbury steak is made by taking the best slices of the "round" of the beef, and chopping it with *dull* knives. The object is not to cut, but rather pound the meat. A hand-chopper can be used, but if the patient is to live exclusively on this diet he would save much time and trouble by purchasing an American meat chopper and having the knives blunted.

The amount of meat used must, of course, be according to the amount a patient can eat. On pounding the meat, as directed, the pulp comes to

the top, and the tough, fibrous portion remains below. This pulp is scraped off and made into cakes—like sausage-cakes—or in shape like a good-sized steak, and *gently* broiled on a gridiron. It has been found that meat gently cooked is more digestible than raw. The fire must be good, so that the meat may be rapidly broiled—that is, be cooked on the outside and almost raw inside.

A little salt and pepper and a small amount of butter added makes a not at all unpalatable dish, and one which contains *all* the strength of the beef, with the tough, indigestible portion entirely separated. This diet is used exclusively in chronic cases, by physicians professing to treat according to the Salisbury method. They use but few drugs, and what they use are mainly tonics. I hope to accumulate the history of cases treated by this method, and if I do so will publish them with pleasure.

This diet is used not only in diseased digestion, but diseases of liver, kidneys, stomach, bowels, nerves, etc., and I have seen remarkable results in persons suffering from widely different diseases.

Freehold, N. J.

The Elevation of the Medical Profession.

Eds. Med. and Surg. Reporter:—

Permit me, through your valuable journal, to express my views in regard to what is necessary to continue the advancement, and elevate the dignity and honor of our noble profession. I say continue the advancement, for the reason that if the past is compared with the present, we cannot help but see great advancement in many respects. But it is also very evident that we are far off from having reached that desired point of dignity and respect that justly belongs to our profession. Many different opinions are being at present advanced on this worthy and important subject. Some seem to think it absolutely necessary to be an A. M. in order to become a qualified physician. In my opinion a requirement of this kind would be a great mistake, as it would have a tendency to shut out from the profession some of the best of intellects, simply because they would not have the necessary funds to attend some school and receive the degree of A. M., while at the same time they might possess a good primary education; in fact better than some that had the funds, if not the brains, to receive this degree. What is true of one degree is also true of another. That the degree of M. D. is not at all times conferred by true merit is sufficient proof to declare the same fault in the degree of A. M. Therefore this is not a force to depend upon. Let us take the material that has force of intellect, no matter whether rich or poor the degree of A. M. or not if they have a good primary education to start with, and the *grit* and determination to qualify themselves in all the necessary branches to make competent and successful physicians. Push, energy, and intellect, backed up by good judgment, is the jewel that we want in order to elevate the dignity and standing of our profession. Inaugurate plans whereby we can reach this important element, and we are then on the right road to success. The physician when he leaves college, after having the degree of M. D. conferred upon him, should not feel and think that he is finished, but should realize the fact that he has but commenced, and should act accordingly, continuing to study and search for knowledge, using every effort to elevate himself both intellectually and morally, and thereby his chosen profession. Some think the physician is not respected as he should be. This is too true; but it does not apply to all. It depends a great deal upon the physician himself. If he is a faithful student, attentive to his business, guarding all his acts and words with good judgment, he must and will command the respect of the community in which he resides.

This great and important duty devolves wholly upon himself, as the degree does not demand the respect from the people it deserves. *Why does it not?* Simply because the degree of M. D. has not been respected by the law of the country until very recently. Consequently, the regular and legal physician was, and, *in fact, is still*, classified in the minds of the people with all the quack, horse and cow doctors of the land. Consequently, if the physician of to-day desires to stand in the mind of the people above these quack doctors, he is obliged to establish qualifications that will place him there independently of his degree.

The next and very important duty devolves upon our colleges. The time that the student serves before he enters college is far too short. In place of admitting them from the blacksmith-shop, the shoe-shop, etc., they should be required to study at least five years under the directions of some regular physician and be examined in regard to their preliminary education before they are received as students at college. If this plan was adopted by the colleges, the registry law enforced, and the respective duties of the physicians adhered to, we would have the power to place the profession in standing where it justly belongs.

C. W. M.

Mainesburg, Tioga county, Pa., December 22, 1884.

The Naval Medical Society.

Eds. Med. and Surg. Reporter:—

The late meeting of this society at the rooms of the Museum of Hygiene, Washington City, Dec. 4, was presided over by Surgeon John M. Browne, in charge of the Museum, and treasurer of the approaching International Medical Congress, Surgeon Charles H. White, Secretary. Among the Fellows in attendance were Surgeon General Francis M. Gunnell, Chief of the Bureau of Medicine and Surgery, James M. Flint, M. D., of the Albatross, C. H. H. Hall, Passed Assistant Surgeon, and Professor H. G. Beyer.

The proceedings and discussions of the society which has a monthly re-union, with the exception of a few months during midsummer, are exceedingly interesting. The papers read continue to present topics instructive and of practical interest to the surgeon and physician. For several weeks past Professor H. G. Beyer has delivered a series of lectures, seven in number, on the "Development of the Chick," illustrated by diagrams, engraving, and models. The theories and opinions of Professor Huxley were most frequently quoted by the learned lecturer, who traced with admirable clearness the development of the higher

orders of vertebræ from the lower series, viz., fish, birds, etc. He described minutely the comparative anatomy and physiology of the fibro-cartilaginous and nervous systems of fishes and birds, and mammals, and proved the wonderful connection between tissues and organs of the inferior and higher orders of the animal kingdom, *e. g.*, that the fish's gills constitute the structural basis of the bones of the ear of the human subject.

The professsion of the metropolis of our country may be congratulated to have presented to them such themes of biological study, since only three universities of America have, as yet, founded chairs for such instruction—that of Virginia was established in 1849, and is filled by Professor I. L. Cabell, President of the National Board of Health.

Among other papers read were:

1. "Cinchona Cultivation in India," by Dr. Geo. W. Wood.
2. "Snake Bites in India," by Geo. W. Wood.
3. "A Memorial Sketch of the Life of the Late Dr. James M. Ambler, U. S. N.," by Dr. Frederick Horner.

The consideration of the history and treatment of a case of acute albuminuria introducing a discussion on the use of opium in such cases, by Dr. C. H. H. Hall, was deferred to the next meeting in January.

During the interval since the writer's attendance at a meeting of the Society marked evidence of the growth of the Museum of Hygiene was noticed, especially in the models of improved methods for the lighting and ventilation of decks and the state-rooms of officers on board ship, and also others presenting a critical analysis of various sewer pipes, showing their construction and defects, the latter due either to the ignorance or cupidity of the manufacturer—though often the occasion of disease and death to our unsuspecting citizens. The library of the Museum continues to receive valuable contributions of books, periodicals, and exchanges from home and foreign publishers. An annual volume, including a synopsis of medical and surgical cases occurring on board of war vessels and steamers of the various squadrons is published by the Bureau. Since nearly one-half of the surgeons afloat and in active service and retired are Fellows of the Naval Medical Society, such publications, with those of the *Transactions*, must contain valuable information.

Surgeon Browne proposes to furnish an interesting exhibit at the World's Exposition in New Orleans of collections from the Museum.

It may not be unbecoming to add that the present efficient Surgeon-General of the Bureau of Medicine and Surgery of the Navy is likely to maintain the high standard of the corps, and will have about him no official unworthy of trust—at least of the mercenary class.

F. Horner, M. D.

Marshall, Va., December 16, 1884.

—The Paris Academy of Medicine, we learn from the *Gazette Hebdomadaire de Médecine et de Chirurgie*, has elected M. Charpentier, the obstetrician, to membership in place of the late Dr. Fauvel.

News and Miscellany.

Royal Doctors.

The *Lancet*, December 6, 1884, says:

It has always been the custom of intelligent princes to acquaint themselves with the studies of their time; and this fact, together with the other advantages of their position, has given them much influence in the advancement of learning. It is new, however, to find them taking a more particular interest in the life-work of their fellowmen, by adopting certain callings as their own—at all events, if we except the profession of arms. This latter, from its close connection with self-preservation alone, other matters being left out of sight, necessarily affects all classes of any people, especially in its earlier history. The peaceful developments of national work, again, belong to an age in which a wiser and more considerate law of comity has succeeded the rule of force, and in which the army has become a highly skilled and heroic form of international police, obedient to that law of order. This, at least, is what ought to be, and what we think has begun to come to pass. It is in keeping with this advance in civilization that members of royal houses in our day have been attracted to take part in forms of labor which, from their wide application, must often present themselves to the minds of all who have the oversight of nations. The name of Prince Albert Victor will shortly be placed upon the student-roll at the Middle Temple, and that of Prince Charles of Bavaria is to be counted among the medical graduates of Austria. It is in various ways advantageous to professional life that royal and noble men should employ themselves in it; and this is no less true of the art which guards the public health than it is of that which stands in defense of civil rule, or of their sister calling which exists to maintain the purity of our common faith. Let us speak of medicine in particular. It is clear, in the first place, that the adhesion of great names cannot in itself ennoble any profession. On the contrary, a profession exercises its government on all who espouse it. Their work is done by its direction, and it is and must be honored, not because of those who do the work, but because of the work which is done. This is pre-eminently true of medicine. Not less true is it that success in its aims cannot be said to wait upon or follow the introduction into it of distinguished persons. The Darwinian law has been well illustrated in its history; it has lived through a long and patient evolution, and has come to be what it is by contact with its circumstances, and, so far, with but little State encouragement. How, then, will it benefit by being connected with the first social and political rank? Partly in this, that the example of men whom circumstances have made independent of the primary needs of existence, and who have been surrounded with many of the less fruitful pastimes of leisure, when they earnestly devote themselves to professional work, is valuable to their fellows. It should impress on all others who are similarly engaged that the highest aim of medicine is not mere gain, either of wealth or of social reputation, but that it touches the life and gratitude of persons and of peoples

in all their interests, physical, social, and moral. The great importance of hygiene among considerations of national management has been recognized by our institution of a Local Government Board, and by many smaller measures. Other countries have acted in a similar sense, and it is satisfactory to find that, with some at least of those who represent the highest political influence, this interest is more than theoretical. We congratulate the royal doctor and others of like mind upon their choice, and we do not doubt that, exercising as fully as they can the varied powers of their profession, they will find that they also are gainers, and that no vocation educates more equally or even more highly the stronger and the finer faculties of our human nature.

Comfort for Invalids Traveling.

An article on Winter Health Resorts, in the *Practitioner*, contains some valuable hints to invalids, to relieve the discomforts found by them abroad in traveling and at hotels. One of the discomforts of the long railway journey which is required in order to reach most health resorts, is the constant vibration and the fatigue it occasions. This may be, to a considerable extent, avoided by the proper use of air-cushions. It is well for an invalid to be provided with two or more of these. The one to be used for sitting on may be either round or square, or may be either with or without a depression in the centre. Air cushions of a horseshoe shape and furnished at the ends with tapes so that they can be opened out and again tied together, are most useful. One of them tied round the loins supports the back, and another just like a collar round the neck supports the head, so that in whatever position it is put, sideways, backwards, or forwards, it always rests against the cushion.

Another comfort to invalids traveling is an India rubber bag for hot water, with a flannel case. Indeed it is well to have two of these if the invalid be very delicate. If any sudden chill is felt, or if any pain in the chest or elsewhere should come on, relief is often obtained by the application of a hot-water bottle which takes the place of a poultice. The invalid's friend can easily get these bottles filled with hot water by giving a small gratuity to the guard of the train, and asking him to fill them when stopping at a station. Stoppages occur on the French lines at least every two hours, and the water retains its heat quite long enough to make it useful between the stoppages.

Another thing which is a great comfort is an eider-down coverlet, which should be both long and broad. It is useful, not only during traveling by land or by sea, but during a stay at the health resorts. One would imagine that an eider-down quilt would be bulky or inconvenient to travel with, but this is not the case. In most "hold-alls" there is a large pocket, and the eider-down quilt can be readily rolled up and put into this pocket. When the straps are once around it, it can, from its softness, be easily pressed into a small bulk.

Two other things that the invalid should not be without are a small etna, with can or kettle, to boil water, and a small package of tea, also beef-tea in a portable form, with a small box of biscuits. Even when such things are to be had at a hotel, the prices put upon them are sometimes so exorbitant that the invalid would hardly care to order them, however much he might desire them.

A War on Quacks in New Jersey.

A dispatch from Trenton, dated January 6, says that physicians in the northern part of the State have been busy for several weeks past preparing a bill to be presented to the next Legislature, that will propose to lessen the growth of quackery and the licensing of unqualified physicians.

The bill as drawn is said to be satisfactory to both schools of medicine. It is in nineteen sections, and provides for the appointment by the Governor of a State Board of Examiners and Licensers.

"It is our purpose," said a prominent physician, this morning, "to subject every graduate or applicant for a diploma to a rigid examination, which will be based mainly upon the fundamental principles of the profession. This plan will, we think, afford better protection to the community, and in time will do away with the bulk of quack practitioners."

The Board to be appointed by the Governor will consist of nine members, who must be graduates of a medical college, and with not less than five years' practice in medicine or surgery.

Seven members are to be chosen from a list submitted by the State Medical Society, and the other two from a list submitted by the Homeopathic State Medical Society.

Two sets of questions will be prepared, each set respectively by the regular and homeopathic societies, and the examination will be in anatomy, physiology, histology, general chemistry, pathology, principles and practice of medicine, surgery, and obstetrics.

The Microbe of Yellow Fever.

At a recent meeting of the Paris Société de Biologie, M. Rebourgeon gave some additional information as to the researches of Professor Domingos Frére, of San Janeiro, on the microbe of yellow fever. He believes that a former communication to the Académie de Médecine has not met with the attention it deserves. M. Frére, he observes, is fully entitled to priority in this discovery, the reality of which is shown by the fatality which attends the inoculation of the microbe in animals, which is very easily brought about. A still more important result is the attenuation of the virus by means to be hereafter divulged; inoculation of this attenuated matter only produces temporary disturbance of the animal's health. Informed of the experiments, the Emperor of Brazil ordered that 600 workmen, constantly occupied in the midst of highly-infected centres, should be inoculated. While before this period ten men out of every thirty had been attacked with the disease, none of those inoculated have suffered, except four of five men, in whom the operation was performed by the lancet instead of by the Pravaz syringe. M. Bouley drew attention to the importance of giving the widest publicity to these statements,

and stated that the attenuated virus was about to be taken to Senegal, where last year twenty-three out of twenty-five French physicians died of yellow fever.

Items.

—Bourgeois, in the *Bulletin Général de Thérapeutique*, recommends the subcutaneous injection of vaccine lymph in place of the endermic method. He has employed the new method with success.

—A department of hygiene and bacteriology has been opened in connection with the chemical laboratory of Professor Fresenius at Wiesbaden. Dr. F. Hueppe, who has done much work under Dr. Koch at Berlin, has been appointed to the charge of this department.

—According to the *Med. Herald*, Dr. Thompson has found the injection of hot water into the nostrils efficacious in arresting epistaxis. The use of hot water as a hæmostatic in other cavities of the body is well known, and it would seem that it is beneficial in hemorrhage from the nose also.

—The *Progrès Médical*, for the 8th of November, 1884, is exclusively occupied by an account of the medical schools, hospitals, etc., in France, and the various lectures delivered at them. It contains more than fifty pages of closely-printed double columns, quarto, and is sold separately; price, sixpence.

—Dr. Collingridge, the Medical Officer of Health for the port of London, has been engaged in Paris in an investigation into the nature and characteristics of the cholera epidemic, the conditions under which it existed, and the special arrangements made for combating the disease, both as regards hospital and sanitary administration.

—Professor Trastor, of Nantes, employs the vapor of glycerine with great advantage when a cough becomes distressing or fatiguing. Fifty or sixty grammes are placed in a porcelain capsule and evaporated over a spirit lamp. An enormous amount of vapor is disengaged. In phthisis and various other affections much relief is gained in this way.—*Revue Médicale.*

—In the *London Med. Times*, December 13, 1884, Mr. Clement Lucas reports a case of irreducible right femoral hernia—operation for radical cure by excision of omental and serous sacs, primary union; and also a case of right inguinal hernia, containing ovary and fallopian tube—operation for radical cure, removal of ovary and tube, and excision of sac.

—In November last Königsberg and Tübingen each lost a distinguished member of the medical faculty. Professor von Wittich died at Königsberg, and Professor K. von Vierordt died at Tübingen. Both of them have long been distinguished in matters connected with respiration and circulation. Professor Kolbe, of Leipsic, author of *Lehrbuch der Organischen Chemie*, died at Leipsic, on November 27th.

—An inspector of meat has been condemned at Halle to a year and a half's imprisonment in consequence of his careless inspection of some pork, in consequence of which ninety persons, inhabiting the village of Strenz-Naundorff, became affected with trichinosis, twelve of the number dying. He had reported the pork in question as free from trichinæ, while he had only examined six of the thirty specimens submitted to him, and these very carelessly, so that a subsequent examination proved that they were infected.

—Fifty years ago there were hardly any such things as dispensaries or out patient departments. Now, in every large city a fourth of the inhabitants (if we go by reports) are annually treated for nothing. The effect has been to make the early attainment of professional skill more easy, but the early attainment of paying professional practice more difficult.

—Studied by their power to prevent the development of micro-organisms in sterilized broth, the biniodide of mercury stands at the head of the list of antiseptics. It is three times as strong as the bichloride. A solution of a $\frac{1}{40000}$ strength renders life impossible to any form of microbe, says M. Miguel, while of bichloride the strength must be $\frac{1}{14000}$. Iodide of silver is also more powerful than the bichloride of mercury.

—A sad case of the suicide of a young surgeon is reported from Vienna. Having been accused of treating an inflamed finger unscientifically, he was fined and sentenced to repeat his examinations. This novel and terrible sentence appears to have so affected him that he drowned himself in the Danube. Meanwhile the verdict was appealed against, and referred to the Doctoren-Collegium, who decided that the dead surgeon's treatment had not caused the loss of the finger in question; and so the High Court acquitted him.

—Drs. Klein and Gibbes have completed their inquiries and submitted a short preliminary report. They state that Dr. Koch's comma-shaped bacilli are not peculiar to cholera, but occur also in other diseases of the intestines; that these bacilli do not behave in any way differently from other putrefactive organisms, and that inoculations of animals with recent and old cultivations of comma-shaped bacilli, as well as with cholera excreta, produced no effect.

—In England, recently, several children were observed to oxhibit all the symptoms of poisoning by morphia. On searching the children's pockets, the source of their illness was made apparent. It seems that some boys stole a seven-pound packet of cough-lozenges, containing morphia, from a wholesale chemist and druggist of Chester, ate a large number of them, and distributed some among their school-companions. The children all recovered.

—At a recent meeting of the Anatomical Society of Paris, M. Babés read a short paper (*Progrès Médical*, December 6), on the comma bacillus in cholera, based on observations made in M. Cornil's laboratory from material obtained during the recent epidemic. His observations, which relate to the morphology of the bacillus and its behavior in cultivation, are for the most part confirmatory of those of Koch. He did not succeed in finding the bacillus elsewhere than in the intestine.

MARRIAGE.

NOBLE—ROSE.—December 18, 1884, at the residence of Thomas Webber, esq., Adobetown, Montana, Rev. Hugh Duncan officiating, Dr. A. G. Noble, of Glendale, Beaverhead county, M. T., and Miss May E. Rose, of Adobetown, Madison county.

THE

MEDICAL AND SURGICAL REPORTER.

No. 1455.] PHILADELPHIA, JANUARY 17, 1885. [Vol. LII.—No. 3.

ORIGINAL DEPARTMENT.

LECTURE.

SOME POINTS RELATING TO EXCISION FOR HIP-JOINT DISEASE.

BY C. B. NANCREDE, M. D.,

Professor of General and Orthopædic Surgery in the Philadelphia Polyclinic and College for Graduates in Medicine.

Gentlemen: This case of hip-joint disease presents some special points of interest, which I shall briefly notice. The history illustrates that which too frequently takes place. First in importance is the fact that the disease progressed favorably under treatment, which was therefore dispensed with at too early a period—at a time when, if persevered in, permanent recovery would have probably ensued. Second in importance is the manifest fact that, had this case terminated by a cure, even without any true articular anchylosis—much more had this existed—a degree of deformity would have persisted, for which there was no necessity. The vast majority of surgeons (and this little patient has been treated by some of the best in the country, having been in more than one well-known children's hospital) consider their active duty over in a case of hip-disease when the child is placed in bed with a weight attached for extension. Now mark what occurs. While the joint's movements are painful, the child will lie down; but just so soon as the treatment shall have relieved these symptoms, the patient sits up in bed, *i. e.*, *keeps the joint flexed*, thus giving full play to the ilio-psoas, rectus femoris, and tensor vaginæ femoris muscles to become contracted permanently, and *they become so*. Mark still further that pressure over the region of the diseased joint creates, at least, discomfort, so that the child rests chiefly upon the sound buttock, thus favoring and increasing the deformity, resulting from anchylosis in the adducted position; so that from these two causes, when the patient gets up the surgeon is disappointed at finding a marked deformity. This was due often also to the omission of lateral support (as by sand-bags) to the limb as it lay in bed, and that no "cradle" was ordered to ward off the pressure of the bed-clothes from the weakened muscles.

My practice is always, under ether, to put the limb as nearly as possible in a perfect position; dividing muscles if necessary, but of course using nothing beyond gentle—although firm—pressure in effecting my point, I do this, not only on account of the future usefulness of the limb, *but to relieve pain*. Many of the most painful joints when "malposed" become comparatively *painless* when placed in good position. I then keep the child on its back by means of a long splint on the *sound side*, extending from the axilla to the foot. A pad under the diseased buttock so as to exert, by the extension, a special stretch on the ilio-psoas muscle, and arrangement of the line of traction of the extension, so as to gradually overcome the adduction, will effect what the first reposition left undone. When I treat a case from the outset, I do not allow this malformation to occur, because I get my patients up with a splint, high slide, and crutches, in a few weeks, keeping them in bed only until the more acutely painful condition of the joint is relieved.

The third point of interest is, that this child's

joint, under ether, seems fairly free in its movements, and that its surfaces did not seem disorganized until I made such free and continued movements as to displace the granulation tissue from the inflamed and carious bone, which was more or less covered in by it. This is not uncommon, even with the inexperienced. A fatally disorganized joint in which suppuration has occurred may deceive, by its apparently smooth, free movements and the absence of bony grating, the tyro into thinking that the profuse discharges and numerous sinuses after all are the result of abscesses not communicating with the joint.

"Starting pains" are beginning to trouble this little patient, and are of peculiar significance. Just in the act of falling asleep, or even while quietly slumbering, the child will suddenly awake with a shriek and a start, and clap its hands to the sore joint, now the seat of an intense though fleeting pain. Perhaps even before the nurse can get to the bedside, the little child again sleeps. By this symptom is indicated hyperæmia and even ulceration of the sublamellar tissues, causing, through direct nervous connection, these reflex clonic spasms of the surrounding muscles.

Commencing amyloid change of the liver was also detectible in this child, and a profuse, exhausting diarrhœa, with hectic, clearly indicated operation or a rapidly fatal termination.

I accordingly excise this joint, and you see that the femoral head is most extensively diseased, and this sinus is the remains of an old interpelvic abscess, the result of extensive disease of the acetabulum, the bottom of which is perforated, while you see this small fragment which I remove in the form of a sequestrum.

As to the indications for excision in hip disease, the history of this case shows that if after keeping the joint at rest by quiet in bed with extension, followed by the promotion of exercise in the open air—the joint being still kept at rest—good food, tonics, and change of air, notwithstanding abscesses form, the health fails, hectic, diarrhœa, starting pains, and commencing amyloid disease show themselves, experience proves that the joint is hopelessly damaged, and that excision or amputation alone can, in most cases, save life.

If extensive amyloid trouble of the liver and kidneys be present, amputation is the better procedure; but when these conditions are incipient, excision is not contra-indicated. This child has since done well.

[The professor described at some length the splints that he preferred in the treatment of morbus coxarius, and went into details that have been omitted for want of space.—Reporter.]

Communications.

THE THERAPEUTICS OF HOT WATER.*

BY CHARLES P. KING, M. D.,
Of Newark, Ohio.

The subject of this paper is the use of hot water as a therapeutic agent. There are many points of interest that I will be obliged to omit entirely, and others I can allude to only incidentally, as the time allotted me is limited. I would like to discuss at length the various modes of administering hot water, such as the hot-air, Turkish, steam, and medicated baths, the mercurial bath, and some others; and while they have a very important bearing on this subject, they are rather beyond the scope of this paper. The use of water in some form or other in the treatment of disease dates back to a very early period.

Our earliest writers make mention of it, and from the days of Hippocrates and Galen down to the present it has had its adherents, and many look upon it as the great panacea for "all the ills that flesh is heir to."

At different times it has been carried to extremes, and has been the instrument in the hands of quacks and charlatans of doing much evil in the world. There are some present who remember what a hold the Thompsonian system had upon the people some years ago, and, in fact, it almost superseded all other systems of treatment for a time; but like many other isms of the kind, has had its day, and been long since consigned "to the tomb of the Capulets."

That the use of water in many of its forms is highly beneficial in the treatment of disease, no one, I think, will for a moment deny. But it should have a place among our other remedies as being but *one* of the *many* means by which we control disease, and we should be very guarded lest we run to extremes in our advocacy of it.

There is fashion in medicine like in everything else; certain modes of treatment are popular because it is fashionable to use them; we have our fashionable doctors and our old fogy doctors; the former being carried away by everything that is new and fashionable—the latter are looked upon as relics of the dark ages whose opinions are entitled to no respect whatever at the hands of their fellowman.

*Read before the Licking County Medical Society.

While many systems of medicine have had their day and been discarded from use, the use of water as a therapeutic agent seems to have withstood the ravages of time, and to-day stands in the front rank as a remedy, both in medical and surgical practice. It is only within the last decade, however, that *hot* water, in contradistinction to cold, has become so generally used. In fact, it has superseded entirely the use of cold water in very many cases.

For convenience of discussion, I will divide my subject into three heads :

1. Use of hot water in medical practice.
2. In surgical practice.
3. In obstetrical practice.

There are many forms of disease in which *hot* water is highly efficacious.

In fevers, for example, many prefer hot water sponging to the cold—the hot to the cold pack.

In all the exanthematous diseases, hot water is not only soothing to the patient, but is also a great benefit in reducing the temperature.

In infantile convulsions, great benefit is to be derived from the hot bath ; in inflammatory affections of the abdominal organs, the use of hot applications has unquestionable value ; in peritonitis, for example, cloths wrung out of hot water, applied over the abdomen, are of great service, not only in allaying local inflammation, but also the general temperature of the body is thus reduced. In inflammatory affections within the chest, such as acute pleuritis and pneumonia, the hot, wet packs are very serviceable ; in habitual constipation, and also many forms of chronic dyspepsia, drinking freely of hot water is of great benefit. Some of the most obstinate cases of constipation have been relieved in this way. As a remedy in dyspepsia, I cannot speak too highly in its praise. I have now under my professional care several chronic cases of dyspepsia which have resisted everything in the way of medicines, and which are now entirely cured by the use of hot water alone. I advise drinking a good-sized coffee-cupful of hot water (as hot as can be borne) three times a day, one half hour before each meal.

In some forms of nervous headache the drinking freely of hot water is of great service; but very recently I saw a statement that many of our members of Congress have been drinking hot water several times a day, instead of their usual potations of whisky.

In some forms of headache, accompanied by determination of blood to the head, the use of hot water freely to the head is of great benefit.

There are many other conditions of the system in which hot water is of great service in medical practice, but for want of time I will be obliged to omit mention of them.

The uses of hot water in surgical practice are both numerous and important. In surgery, as in every other department of our profession, simple methods of treatment commend themselves to the careful practitioner. For this purpose I desire to direct your attention to an agent simple, cheap, and of easy application ; this is the use of hot water.

It is to the value of hot water as a *hæmostatic* agent, however, that I wish to direct chief attention, especially to its power when the bleeding is from small vessels, or of that character denominated capillary bleeding or oozing—a fact first brought prominently to the notice of the profession by Dr. Emmet, of New York, in his great work on gynecology.

He has been magnanimous enough, however, to give the late Dr. Pilcher, of Detroit, Michigan, the credit for having first called his attention to it ; he says "that while operating in 1859 to close a vesico-vaginal fistula, where free incisions were necessary, the progress of the operation had been greatly delayed in consequence of oozing of blood; this could be temporarily checked by pressure and ice, but in a few moments reaction would take place and the bleeding be as great as ever. Dr. Pilcher being present, he suggested that a sponge probang be dipped in hot water and applied several times to the bleeding surface. This was done, and the bleeding promptly arrested.

Cold water and ice even are much less efficient in checking hemorrhage than hot water. The immediate effect of cold is to *contract* the bleeding vessels, but this contraction is very soon followed by the opposite condition, dilatation ; one that continues for a considerable period, and one that favors further hemorrhage.

Besides, it is a fact well established that prolonged cold lowers the reparative power of tissues. The immediate effect of heat is to dilate the vessels, but it afterwards contracts them.

The manner in which hot water arrests hemorrhage is that the clot formed in the mouth of the dilated vessel is held so firmly in position by the subsequent contraction as to prevent its being readily dislodged. One of the principal advantages that hot water has over all other agents employed, is that it does not interfere with the subsequent healing process ; in fact, it is thought by many to promote it. As a dressing for wounds, contusions, and inflamed parts in general, it is

invaluable. The cold-water treatment of wounds is very often highly injurious, the circulation in the wounded parts being too much depressed, which of necessity will hinder repair, and sloughing is often induced.

In ovariotomy there is frequently a good deal of oozing of blood that must be arrested before closing the abdominal cavity. In such cases the frequent application of sponges dipped in hot water will generally promptly arrest the hemorrhage, even in cases where persulphate of iron has failed.

In cases of removal of uterine fibroids, the injection of hot water into the uterus succeeds in arresting hemorrhage which would otherwise require the use of the tampon. After amputations where there is much oozing of blood from stumps, in excision of mammary glands, and various other operations, hot water is of great service.

In hemorrhage from the nose, the injections of hot water have proved of great service in the hands of some surgeons; in pulmonary hemorrhage the inhalation of hot water in the form of steam is said to be a most valuable agent. Prof. Hamilton, of New York, has of late years strongly urged as a preventive measure against traumatic inflammation the use of warm water instead of cold, and of immersion as superior to irrigation. He places the injured part in a water-bath, constantly maintaining a temperature of 90° to 95° F., and keeps it there from one to three weeks. When from the position of the injury this is not practicable, he covers with several thicknesses of sheet lint, previously saturated with tepid water, and encloses this with oil silk. When the bath can thus be employed, little or no inflammatory reaction takes place, and gangrene is very successfully arrested, even in exceedingly severely lacerated and contused wounds of the extremities. Dr. H., from an extended experience, much prefers this to the cool or cold prophylaxis of inflammation. In painful hemorrhoids, where there is much tenderness and considerable hemorrhage, the use of hot water locally as well as by injections, is not only exceedingly grateful to the patient, but is also a prompt and efficient means of arresting severe hemorrhage.

The uses of hot water in obstetrical practice are as important as in medical or surgical practice. Our leading gynecologists are fully aware of its value, and make extensive use of it by vaginal injections to relieve congestions and inflammations of the pelvic organs. And while (as Dr. Emmet says) "it is not the cure-all for these affections," it is of such great value, that were its worth generally known much of the cauterization, intra-uterine medication, scarification, and other operative measures, would be done away with, greatly to the relief of suffering women."

Hot water injections, or the hot douche, is one of our most effective measures to be used in chronic metritis.

Large quantities of water, and frequent applications, are needed to produce the best results.

Excellent results are often obtained by the alternate use of the hot and cold douche.

In severe cases of hemorrhage resulting from abortion, it is an admirable remedy in checking the hemorrhage, by producing rapid and permanent uterine con'ractions.

Not long since, I succeeded in controlling one of the worst cases of uterine hemorrhages I ever saw by the use of hot-water injections thrown into the uterine cavity.

In severe cases of post-partum hemorrhage the hot-water injections into the uterine cavity are of great service.

In obstinate cases of chronic inflammation of the os and neck of the uterus, the frequent applications of hot water into the vagina are of great service; in cases of leucorrhœa resulting from a want of tone in the mucous and muscular tissues of the vagina, hot-water injections are par excellence the remedy mostly to be relied upon. After severe labors, where there is much tenderness of the parts owing to the great strain, the daily injections of hot water are of great service, not only on account of their soothing effects, but also as a means of preventing inflammation of the uterus and its appendages.

I am satisfied that many cases of child-bed fever, following protracted labors, might be prevented entirely by the frequent use of hot vaginal injections.

Says Professor Lusk: "Putridity creeps up from the vagina, which should be thoroughly washed out. In normal labor the hand, and sometimes instruments, carried into the uterine cavity, may necessitate washing, which may be the direct means of saving life. Wash out the uterus thoroughly with carbolic acid solutions, or other disinfecting fluids."

Since the introduction of this plan by our Continental physicians, the per cent. of cases of child-bed fever has been very materially diminished.

Dr. R. H. Gunning, member of the Royal College of Physicians of London, recently read a paper before the Medico-Chirurgical Society of Edinburgh on the "Gynæcological Uses of Hot Water," from which I clip the following:

"Ladies suffering agonies in menstruation are better relieved and cured by very hot hemicupia than anything else. Of course, complications must be attended to at the same time; the bowels need attention, or a weak circulation or cold extremities may need a hot stimulant—hot punch; but such complications being attended to, a hot hip bath is the safest means, not only in relieving painful menstruation, but when defective or in excess—used for successive periods—the first is increased, the second is diminished. In acute leucorrhœa or irritated rectum, in the tenesmus of diarrhœa, besides the hip bath, hot water simply or medicated with opium can be injected into the passage. I even use a very warm hip bath after labor, when the lochia are excessive and the patient is feverish. In this way, ablution is effective, the parts are soothed, and a source of puerperal fever, especially in warm climates, is removed. I have the patient carefully lifted and set down in a very plentiful and hot hip bath. A recent illustration of the use of hot water occurred to me in Italy. A lady's absence from the table at the hotel was daily regretted by her husband and friends, and medicines were doing her little good. I found she had had an abortion about a month ago, and that the hectic and lassitude were due to the painful post-partum hemorrhage. I advised her to sit down at once, and again and again, in very hot water, and also to inject it plentifully. She was soon relieved, and on the second day was at the table and out everywhere, quite well."

Playfair invariably recommends intra-uterine injections in the puerperal bed. He says: "They should never be omitted in all cases in which self-infection is possible; and, indeed, even when there is no reason to suspect the presence of a local focus of infection, the use of antiseptic lotions is advisable as a matter of precaution, as they can do no harm, and are generally comforting to the patients."

It is not necessary to use intra-uterine medications in *all* cases in the puerperal state. Where the system begins to show evidence of general poisoning, and there is reason to suspect a putrid material within the uterus, then this mode of treatment is in the highest degree imperative.

There are many other conditions in which the use of hot water is of great service in obstetrical practice, which I would like to refer to, but fear that I have already taxed your time and patience entirely too long.

In conclusion, I would say that whatever may be the mechanism through which the effect is accomplished, I have been taught, both by experience and observation, that hot water is a simple, cheap, and effective means for attaining good as well as permanent results, in both medical, surgical, and obstetrical practice.

MISCARRIAGES.

BY E. H. COOVER, M. D.,
Of Harrisburg, Pa.

The frequency with which miscarriages occur, the alarming extent to which abortions are procured by females, married and single, upon themselves, to avoid the care of children upon one hand and shame on the other, the danger and suffering entailed upon them, and the increased number of embryonic lives wantonly destroyed, call for a careful study of the symptoms, diagnosis, and treatment, by the conscientious practitioner who looks upon the practice of his profession in a higher sense than as a mere source of pecuniary advantage.

It is a subject which I consider has been in a great measure neglected, although several very eminent professional gentlemen have given to the annals of medical science opinions, the result of experience, which have proved valuable acquisitions, and by their timely precepts saved many valuable lives. With a view to the furtherance of useful knowledge in this direction, and in the indulgence of a hope that an an experience gathered in a large practice, covering a period of over thirty years, may enable me to throw some additional light upon a subject which must be of interest to every physician, I offer the following, and in doing so beg the indulgence of the reader for all deficiencies:

Causes.—The causes which lead to the destruction of embryonic life, and the premature arrest of utero-gestation, may be classed as predisposing and exciting. Among what may be termed predisposing causes may be enumerated general irritability of the system, deficiency in the nutritive function, the susceptibility of the uterus to sympathetic affections, *uræmia*, and some forms of *toxæmia*.

The exciting causes are the application of violence either directly to the uterus itself or to some distant organ which may in return by a sort of reflex action exert an influence upon it, jumping from a height, falling down stairs, sudden fright, blows upon the abdomen or back, the internal introduction of knitting or crochet needles, the use internally of highly stimulating decoctions and active purgatives, all form exciting causes, and are fruitful agents in bringing on abortions.

My own experience, however, has been that of all causes, except those intentionally procured, *reaching overhead* is the most frequent source, and a habit which every pregnant female should guard carefully against.

Symptoms.—The symptoms by which abortions are preceded are as varied in their peculiarities as the causes which lead to them. There are, however, a number of general symptoms which are unmistakable in their character, and point significantly to the commencement of an abortion. There is pain in the back and pelvis, coming on and going off with the character of labor pains. In many cases it will only be a backache with feeling of dragging and weight in the pelvis until the discharge of blood becomes free, sometimes sudden and copious, at other times slow and gradually increasing; then clots are passed, and the woman feels exhausted. Sometimes the pain is slight and the hemorrhage copious, and at other times both are slight, yet continuous, until the ovum is destroyed without expelling it.

An examination now shows the os dilated more or less; the internal os, as a rule, is further dilated than the external os. The cervix seems conical and directly continuous with the line of the body of the uterus; where the process has lasted considerable time, a cadaverous odor in the discharge, or on the hand after an examination, is noticeable, which, in itself, is sufficient evidence of the presence of a devitalized ovum.

In many cases where the female does not know herself to be pregnant, and having been accustomed to copious menstrual discharges, a hemorrhage, occurring after having passed one or more periods, may be mistaken for an excessive menstrual discharge. This is particularly the case when the patient believes, as many do, that having missed a period, the next one following should furnish a more abundant discharge. It is, therefore, very important to note whether the discharge is a regular oozing flow; or whether at the time it spurts out as if forcibly propelled along the inner surface of the thighs or along the hand and forearm of the physician during an examination. If the latter is the case, it may be taken as an unfailing symptom of abortion, as no menstrual flow is ever expelled, the discharge having that hot feeling and with sufficient force to produce the like.

Diagnosis.—In order to arrive at the correct diagnosis, it is necessary to take into consideration all the conditions; for upon these the treatment is based, and upon the treatmeut success depends. The physician will be greatly aided by having all the discharges carefully preserved, and subjecting them to a critical examination. The practical eye will soon detect any portion of the ovum which may have been detached, and be better enabled to make his diagnosis and prognosis.

It is always well to suspect miscarriages when there is pain and flooding; and if the patient has had previous miscarriages, that fact alone is significant in making up the diagnosis.

Prognosis.—When the habit has been established, it is safe to conclude that it will occur again, and it is very difficult to prevent it.

After pain and hemorrhage have set in, abortion has already commenced; and where the discharge has been abundant and the pain severe, to attempt to arrest the process by the use of astringents or styptics would be but to prolong the suffering of the patient. But even in such cases it has stopped and the pregnancy gone on to full term. If an examination show a dilation of the os and protrusion of part of the ovum, or even a clot, we will be satisfied that it will go on. If pain is present without hemorrhage, the process may be arrested by proper treatment. If there is hemorrhage without pain, the aspect is not wholly adverse, but I regard homorrhage as an adverse symptem, as it shows a more or less separation of the ovum from the walls of the uterus, thereby endangering its vitality. So long as the os is not open, and the sphincter muscles preserve their rigidity, there is yet an opportunity to prevent a miscarriage by appropriate treatment; but when once open, the use of astringents, either administered internally or applied locally, is vain, and abortion must follow.

Treatment.—It frequently occurs that the physician is not called until the symptoms have become alarming to the patient or those about her, and when he arrives he finds her in a state of great alarm. She fears she is about to bleed to death, and her whole nervous system is wrought up to a high degree of tension. To calm her fears and reduce this difficulty, I am in the habit, if there is much pain, of administering a dose of morphine. If the pain is not severe and the nervous sensibility great, I give bromide of potassium; and if both are present and equally severe, I combine the two in quantity and proportion as meets my judgment at the time. I find this course very useful as a preparation for further operations. If the os uteri is closed and a careful study of the condition affords the belief that a miscarriage can be prevented, I administer narcotics; if the stomach is sick, nux vomica, and bathe the lumbar region of

the spine and abdomen with a mixture composed of one part of chloroform and two parts ether sulphuric. The rapid evaporation of this compound from the surface of the skin makes it refrigerant in its action, and produces a sedative effect upon the parts to which it is applied. This also being grateful to the patient, aids materially in calming her nervousness and securing a condition of rest often valuable in arresting acute symptoms. When the hemorrhage is so excessive or long-continued as to cause alarm or produce a condition of syncope from exhaustion, active measures are required. If the os is sufficiently dilated to admit of the passage of the index finger as far as the second phalanx, or through the external into or through the internal os, I introduce it, preferring the right hand, and by a sweeping circular motion I either break away that portion of the placenta adhering thereto, as far as it can be reached; or if it is not possible to pass the finger any further than into the external os, I perform the same operation, thereby irritating the uterine nerves.

The conditions under which this operation would apply are not infrequent, yet they only constitute a minority. In the majority of cases the os is sufficiently expanded to separate the placenta, which can be easily removed by inserting the finger and hooking it out. In cases, however, where the os is not sufficiently dilated, the operation above referred to is far more sure and speedy in arresting hemorrhage than the use of tampona or the dilation of the os by means of sponge-tents. I have never failed in a single instance to arrest hemorrhage at once by this method, when the conditions were as above stated. The reason is plain; as soon as the uterine nerves are irritated, or that portion of the placenta adherent to the internal os is separated, the blood-vessels contract, and by the rapid formation of coagulum, a natural mechanical barrier is opposed to the further effusion of blood. If the patient is in a state of syncope the result is more speedy, as the condition is always more favorable to the coagulation of the blood and the formation of the clot. The hemorrhage arrested, I assure the patient that her bleeding is over and leave her to rest in quiet, awaiting the natural expulsion of the ovum, which may occur in a few hours, or perhaps not for days, weeks, or even months; yet it will come sooner or later, and with less suffering and danger to the patient than if removed at once by force. The placental attachments are often sufficient to maintain their vitality for some time.

I may here state, that in my practice I have never found the use of instruments necessary. I have been upon several occasions recalled, but in every case found the return of hemorrhage due to the result of failure to fully enter the external or internal os. All such cases were met by the administration of the fluid extract of ergot, or tamponed. With the detachment of the placenta there is usually an arrest of hemorrhage; even though the ovum has not been passed, the danger may be regarded as very much lessened. But the question will be asked, "What are we to do if the after-birth does not pass?" If the os is dilated and you can remove by hooking the finger over it, and with pressure over the uterine globe through the abdominal walls and the bearing efforts of the woman, it may be carefully removed. If it cannot be removed in that easy manner of procedure, wait until it passes away naturally, even though it decompose and pass off as an offensive discharge; there may be more safety than with ordinary rough usage.

This, however, is seldom the case in pregnancy of two months or less, of which I am specially treating in this paper.

After-treatment.—The first indication in the after-treatment is rest. I recommend the patient to remain in bed at least nine days in order to avoid accidents, which are liable to occur during that period. This period of time is specifically regardless of the discharge of the after-birth. If it has passed out before the expiration of the nine days, it is well; if not, it does not matter. I consider the patient at that time out of all danger from causes resulting from her premature delivery. If patients would more generally obey this direction, there would be fewer cases of diseases peculiar to women who have passed the period of maternity.

Diet.—As regards diet, I am generally disposed to be somewhat liberal. A tender piece of beef-steak or lamb chop, or soft-boiled egg, may be allowed, and will, in the majority of cases, be more advantageous than injurious. Strict regimen in diet, I believe, has a tendency to retard recovery, by withholding necessary nutriment.

Cleanliness.—In order that every possible comfort may be used as an auxiliary for the promotion of recovery, I direct that the garments and bed-linen be frequently changed, and the skin be cleansed by occasional ablution by means of the sponge-bath. By removing the secretions frequently a healthy action is engendered, and the skin made to perform its functions naturally. The bed-clothes should be light, and the temperature

of the room regulated in accordance with the comfort of the patient. Attention to the condition of the bowels is important. When a disposition to constipation is manifested, I generally administer a mild purgative. Plenty of light, fresh air, and cheerful surroundings, are valuable adjuncts in promoting rapid convalescence.

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE PHILADELPHIA HOSPITAL.

BY JAMES TYSON, M. D.,

Physician to the Hospital and Professor of General Pathology and Morbid Anatomy in the University of Pennsylvania.

Reported by WILLIAM H. MORRISON, M. D.

Emphysema.

GENTLEMEN: I wish to-day to call your attention to a very important series of cases which illustrates a pulmonary condition not always easily remediable, but at the same time so imperfectly understood in that which essentially constitutes it, that I am quite sure a more thorough understanding of the condition will lead to more successful results in treatment. I allude to that condition known as pulmonary emphysema, or emphysema of the lungs.

There are two applications of the term emphysema, and they have very different significations. In the first place, it is applied to what might be called an infiltration of the soft tissues, including the interstitial tissue of the lung, with air or gas. Most frequently the source of this air is a wound of the lung, as a result of which, at each inspiration, air enters the connective tissue and infiltrates it, producing on pressure a peculiar cracking sensation, readily recognized. In such cases, the emphysematous condition is found more particularly in the chest walls, but any other connective tissue of the body may become pervaded with the air, and give the peculiar crepitation to the fingers. Again, the emphysematous condition may be due to the infiltration of the tissues with gas, the result of decomposition. It is sometimes found in the neighborhood of wounds which take on an unhealthy action, and where decomposition leads to the generation of gas. This form of emphysema is, of course, more circumscribed than that due to a wound of the lung.

The form of emphysema to which I desire to call your attention is a very different condition from those which I have described. It consists primarily in a simple dilatation of the air-vesicles of the lung. The subsequent fusion of adjacent dilated air-vesicles, leads to the development of what suggest little blisters or bullæ, varying in size, over a greater or less area of the lung. They are found more particularly at the edges and apex of the lung. More commonly, this emphysema is what is known as lobular; that is, the air-vesicles going to make up a lobule have become dilated, the partitions, separating one from another, have been broken down, and a bladder is produced the size of the lobule. The condition may, however, involve a lobe, or an entire lung. This, in a few words, is a description of the affection which I propose to illustrate by these cases, which jointly, I think, will afford all the symptoms which are met with in this condition.

The history of the first patient is as follows:

"John M., aged fifty-eight years, laborer, was admitted to the hospital in September, 1883. He began to ail a year earlier, the symptoms being pain in the infra-axillary region of the right side, shortness of breath, and slight cough. During the following winter, he was obliged to stop work on account of an aggravation of his symptoms. He received no treatment, but began to improve towards spring, and was then able to walk, but not to work. Since admission into the hospital, he has complained of great weakness and shortness of breath on exertion. There has been some cough and a viscid, yellowish-white expectoration."

I wish you to note that the cough is slight, while the shortness of breath is great.

In the physical examination of the case, I shall first call attention to the facts learned by inspection. Observe, that although he is emaciated, how prominent the upper front part of the chest is, how marked both as to depth and width are the intercostal spaces, how with each act of inspiration the lower part of the chest below the nipples is drawn in, and how the intercostal spaces are seen with increased distinctness. Observe the depth of the supra-clavicular fossæ and how their depth increases as he breathes; how the scaleni and other muscles which move the upper portion of the chest walls, do a large part of the work in drawing up or attempting to draw up the clavicles. Observe that although breathing with considerable effort, how little the upper part of his chest moves as compared with that of a man in health. On the other hand, the upper abdominal region, in which the diaphragm plays, is characterized by considerable movement. Posteriorly, observe the great prominence of this portion of the chest, which in a general way may be compared to the shape of a barrel. This is, however, not so marked in this case as in another which I shall show you.

Let us continue our physical examination by percussion and auscultation. Observe the marked resonance obtained by percussing over the anterior portion of the chest. Of course, as his is a thin-walled chest, we should expect it to be more resonant than if covered by a thick layer of fat: but even independent of this, it may be said that the chest is more resonant than is normal. This hyper-resonance may be said to pervade the whole of the chest, back and front, although in some places it is more marked than in others, as for instance in the region below the left scapula, as compared with that below the right.

Before auscultating, let us reason to the signs which we should naturally expect to find in such a case. Remember, if you please, that these air vesicles are dilated, and that they are not only dilated, but that the walls separating the individual vesicles are broken down, so that a number of vesicles are thrown into one cavity. Under such circumstances, the elasticity of the walls

must be lost. A large degree of the efficiency of the act of expiration is dependent on the elasticity of the air vesicles, and in the absence of this elasticity, it is evident that the air can be but partially expelled. There is no obstacle to the entrance of air into the vesicles, nor any to its outward movement, but the *vis a tergo* is wanting.

We should, reasoning from these facts, in a typical case of emphysema, expect to have a short inspiratory sound and a prolonged expiratory sound. This is exactly the reverse of what is found in health. There the inspiratory sound produced by the bronchial and vesicular elements is long, and the expiratory sound is short. In point of fact, we do not have in emphysema these sounds exactly as I have described them, because emphysema is rarely an uncomplicated affection. It is often associated with bronchitis, and it is constantly accompanied by spasmodic contraction of the bronchial tubes or asthma. The typical sounds of emphysema are therefore usually complicated with the sounds attributable to these affections. Let us listen in this particular case, and observe the signs that are present.

On the right side below the clavicle there is a sub-crepitant, that is a small bubbling rale. It is a bubbling sound larger than a crepitant, and smaller than a mucous rale. When I again place my ear over the spot, the sound has disappeared, showing that it was due to little mucus, which has become displaced, and the rale is replaced by an inspiratory murmur, which is not much altered. The expiratory murmur is distinctly prolonged. As I carry my ear downwards over the right chest, I note the continuance of the rough, short inspiration, and the prolonged feeble expiration. In the right axillary and infra-axillary regions, the sounds are tolerably normal. Below the left clavicle there is rough inspiration and prolonged expiration. As I pass downwards, the prolonged expiratory element continues, while the inspiratory element is more natural. In the left axilla, I note the feeble prolonged expiration as the most marked feature. Posteriorly, in the supra-spinous fossa of the right side, I cannot say that the sounds are materially altered. Below the spine of the scapula, the prolonged expiration makes its appearance. Below the right scapula the sounds do not differ much from those of health. On the left side expiration and inspiration are natural above the spine of the scapula. Over the scapula I begin to hear rough inspiration and prolonged expiration. Below the angle of the left scapula the sounds are not materially altered.

Let us now turn to the second case, of which we have the following history: "Jacob S., age 34, a widower, a watch-maker by occupation, entered the hospital September 1, 1884. His family history is good. He has been a moderate drinker. Fourteen years ago he had a chancre with the usual secondary symptoms two years later. He has had pneumonia twice on the left side, the first time five years ago and the second time two years ago. He has been admitted to the hospital seven or eight times for the present trouble. This dates back to a cold which he caught five years ago. At that time he suffered with pain in the chest and shortness of breath. These symptoms have continued with a gradual increase in severity up to the present time. With this there have been frequently recurring attacks of asthma. There is more or less constant cough, which is often paroxysmal. It is accompanied with considerable expectoration, and is worse at night. The appetite is good, and the bowels are regular. For about a year a ventral hernia caused by the coughing has been present."

The difference in the history to which I wish particularly to call attention is this, that this man has had a great deal of cough, while the other man had but little cough.

Another fact in his history is interesting as bearing on the etiology of the affection. The man is by occupation a watchmaker, and for the past eighteen or twenty years he has been compelled to use the blow-pipe for fifteen or twenty minutes at a time two or three times a week. I shall refer to this again in discussing the etiology of the affection.

This case has lasted longer than the preceding one. The appearance of his chest also differs materially from that of the first man. It is well covered with fat. Notwithstanding this, if the breathing is carefully watched, sulci are observed above the clavicles, and although he is making considerable effort in breathing, the upper part of the chest moves but slightly. The mammary region is conspicuously prominent, and below the mammæ, on each side, the ribs are retracted in breathing, not markedly, but sufficiently to disclose distinctly the intercostal spaces. In the epigastrium is observed the prominence due to the ventral hernia. The strains to which the fibres of the recti muscles have been placed in the act of coughing has caused them to separate, and the abdominal viscera project each time he coughs. The "barrel" shape of the thorax is here more easily recognized than in the previous case. Note the greater prominence of the right side posteriorly as compared with the left. There is a protrusion of the region below the right scapula. It might at first sight be thought that this is due to unequal development of muscle, but a little examination shows that the ribs are immediately under it, and there is therefore no doubt that there is protrusion of the ribs at this point. We should expect theoretically to have increased percussion resonance over this bulging portion, and such proves to be the case, showing that the right lobe of the lung is more emphysematous than the left lobe. Percussion gives a general hyper-resonance which is however most marked below the right scapula. But the typical auscultation signs of emphysema just described are overshadowed by the sonorous and sibilant rales which, caused by the asthma, complicate the emphysema.

I present you a third patient, whose history is as follows:

"Jacob R., aged fifty-nine, unmarried, a farmer by occupation, and later a hostler, was admitted to the hospital ten years ago. The present affection dates back twenty years, at which time he caught cold from going in and out of an ice-house. He has had a troublesome cough, with considerable expectoration, and shortness of breath ever since. He was, however, able to work up to two years ago. Of late years, he has also had frequent attacks of asthma."

Inspection again reveals depressions above the clavicles, and there is a prominence of the entire præcordia. All that region occupied by the sternum in front, and the cartilages, as far as their junction with the bony ribs, is unusually distinct. Observe, also, the slight degree of movement of the chest, although the breathing is labored. We note, also, the exaggerated movement of the upper abdominal wall and the increase in width of the intercostal spaces during the act of inspiration, although this is by no means as marked as in the first case. Posteriorly can be distinctly seen the "barrel" shape, much more marked than in either of the other two.

I also call attention to the displacement of the heart. The situation of the apex beat, instead of being an inch below and within the nipple, is fully two inches below it, and the area of cardiac dullness is much diminished. This is a striking symptom of emphysema, and in this particular case, is very conspicuous.

Both the displacement of the heart and the diminished area of cardiac dullness are both due to the enlargement of the lungs, the heart being pushed downward by the enlargement in the vertical direction, and covered by the extension of the edges of the lungs anteriorly. For the same reason the liver is also pushed downward.

In addition to the facts already mentioned in connection with these cases there is a most marked change in the antero-posterior diameters of the chest, which can be best appreciated by a lateral examination. In case 2 the antero-posterior diameter is fully as great as the transverse.

As to the *diagnosis* of emphysema, the conditions with which it is most likely to be confounded are pleurisy and pneumothorax, but there should be no difficulty in the diagnosis. As you well know, there is in pleurisy also a bulging of the chest, but in the bulging of pleurisy, although there may be tympanitic resonance above the level of the effusion, yet over the most prominent portion of the chest, there is dullness or flatness on percussion, and the intercostal spaces are prominent rather than depressed. There is in pleurisy the same shortness of breathing and the same effort at breathing. The physical signs are however so different that there should be no trouble in the diagnosis.

In pneumothorax there is a closer simulation of the physical signs of emphysema. There is also bulging of the chest, which is, however, usually more marked on one side than on the other, but as it is rather rare to have a uniform, symmetrical emphysema, we may have here also a greater prominence of one side than of the other. It is said that the parts of the lung most likely to be affected with emphysema are the upper part of the right lung and the lower part of the left. So in the matter of percussion, both emphysema and pneumothorax give hyper-resonance. Pneumothorax, however, gives more marked tympany than emphysema. It has always seemed to me that the books rather exaggerate the clearness of resonance found in emphysema. The hyper-resonance, although marked, is not always so striking as we are lead to believe. In the hyper-resonance of pneumothorax there is a real tympany, comparable to that obtained over the distended abdomen. In pneumothorax there is very frequently metallic tinkling, caused by the dropping of fluid from the perforation in the lung into the pleural sac. In the lower portion of a chest with pneumothorax there is always effusion, which gives dullness on percussion, and a line of separation between the tympany and flatness is demonstrable. Pneumothorax is sudden in its occurrence, whereas emphysema developes gradually. It is, however, not impossible for the two affections to be combined.

There is still another condition with which emphysema might be confounded, but this is so rare that unless one's attention were drawn to it from his personal experience, he would not be likely to think of it. The condition to which I refer is diaphragmatic hernia. This is an uncommon condition, but when it does occur it gives rise to tympanitic resonance in the chest. To my mind the possibility of this condition is always present, because of personal experience.

I had under my observation for a long time a very singular case, in which there had been a rather sudden development of symptoms. The condition came on suddenly while engaged in a scrimmage or wrestle. He was seized with a sudden sharp pain in his left side, and a day or two later he began to have a peculiar puffing respiration. With this there was extraordinary clearness on percussion over the region of the left lung. He was examined repeatedly by myself and others, but no one thought of the true cause. None suspected diaphragmatic hernia. The autopsy showed that almost one-half of the abdominal viscera were in the left pleural cavity, and that the lung was pushed into the upper portion of the chest, occupying a space about the size of the fist. This man presented the bulging, the shortness of breath, and the hyper-resonance peculiar to emphysema. Having once met such a case, one is apt to be on the look-out for it again. I therefore mention in passing that diaphragmatic hernia may produce physical signs simulating those of emphysema.

We next come to the *etiology* of emphysema. By far the larger number of cases of emphysema are the result of chronic bronchitis. This bronchitis, which may have for its consequence emphysema of the lungs, may begin in childhood; it may begin as whooping-cough, from which the child has not completely recovered, or succeeding which it has been subject to constantly recurring attacks of bronchitis. It may occur later in life, as the result of exposure to cold and recurring attacks of bronchitis. It is scarcely likely if the lung preserved the proper integrity of its tissue, that even under the forced strain of coughing it would undergo the dilatation and destruction which occurs in emphysema. Sooner or later, with chronic bronchitis, there is a change in the integrity of the tissues of the air-vesicles, which makes them more yielding and more likely to give way under strain. It has been stated the blowing on wind instruments is a cause of emphysema, but this is by no means a settled fact. It is not impossible in a case where there was chronic persistent bronchitis, with the alterations of structure which occur in this disease, that blowing on wind instruments might produce emphysema. That this is of itself sufficient is hardly likely. It will be remembered that one of

our patients is a jeweller, and has worked a good deal with the blow-pipe, using it several times a week, and keeping it up for a length of time. The effect of this would be similar to that of blowing on wind instruments. The prolonged, full inspiration, and the long, forced expiration, would naturally tend to produce dilatation of the vesicles. That it is of itself sufficient to produce this dilatation has not been established, but as I have said, it is not impossible that in connection with chronic bronchitis, and the changes in texture which occur in this affection, it may assist in the production of emphysema.

Again, it is hardly likely if all parts of the lung are equally free to the entrance of air, that the forcible inspiration and expiration which constitute coughing would produce the over-dilatation of the vesicular structure. We are in the habit of saying that emphysema results from inspiratory and expiratory strain. I am inclined to believe that strain of the lung occurs more commonly in the act of expiration than in inspiration. As a result of the chronic bronchitis, certain tubules become plugged with mucus, which acts as a valve, permitting the entrance of air, but not allowing of its exit. Finally the vesicles become filled with air, which cannot be passed out. In the act of expiration, the lung is compressed, and the air is forced back into all the little corners; the air cannot get out, while at the same time the lung is being squeezed; it is forced in the direction of least resistance towards the air vesicles, and dilatation takes place in the apices and edges of the lungs. This is probably the way in which expiratory strain acts in producing dilatation.

Over-distension may also result from forced inspiration. As the result of the chronic inflammation of the bronchial mucous membrane, certain parts become plugged with mucus, but the valvular action is in the opposite direction, permitting the air to get out, but preventing it from getting into the vesicles. A certain amount of air enters the lung with each inspiraiion, but if a portion of the lung is cut off, the air must go elsewhere, and the remainder becomes the seat of what may be termed collateral aeration. This produces an undue distension of the air vesicles, and they yield to the dilating force. It is evident, however, that the dilating force thus exerted cannot equal that in expiratory strain, and I say again, therefore, that expiratory strain acts more potently than inspiratory strain in producing emphysema.

As a result of the over-distension of the air-vesicles, there is first dilatation, then the walls of the vesiele atrophy, and with the atrophy of the walls the blood vessels surrounding them are destroyed. Although under these circumstances the lung occupies more space, its blood aerating power is diminished. The circulation is cut down to the larger trunks, and the blood, as it were, takes a short cut from the pulmonary arteries to the pulmonary veins. The aeration of the blood is thus rendered difficult or impossible, accounting thus in part for the dyspnœa.

This symptom of shortness of breath is also partly due to the fact that the air the vesicles does not change. One of the most important results of emphysema is the loss of elasticity in the walls of the air vesicles. The intercostal muscles, the diaphragm and auxiliary muscles of respiration, enlarge the thoracic box, and the lungs expand to fill it by their own resiliency, producing the act of inspiration, while the air is expelled in expiration partly by the recoil of the elastic tissue and partly by the pressure of the contracting thorax. This natural resiliency is absent in cases of emphysema. The lung is always filled with air, but it is air charged with carbonic acid, and does not change. As a consequence, the patient makes increased efforts to draw the air into the lungs, but as the air vesicles are already filled with air these efforts are ineffectual.

As to treatment, it is impossible, so far as we know, to restore destroyed lung texture. If a number of air-vesicles have been converted into one sac or bladder-like cavity, I believe that there are no means by which these vesicles can be restored. At the same time, where we have youth on our side, there is some, if the structural loss is not too great; its functions may be supplemented through the natural recuperative tenderness of the economy. Our efforts must be directed mainly to averting those conditions which complicate and increase the emphysema. As I have said, chronic bronchitis is its most frequent cause, and, therefore, we must try to relieve this condition by every means in our power. At the same time, the general health is apt to be impaired, and it is as important that this should be restored as that the bronchitis should be relieved. The blood is to be restored to a proper composition by tonic remedies like cod-liver oil and iron, and the use of the very best food that the patient can procure. To the cod-liver oil and iron I always add strychnia in full doses, $\frac{1}{30}$ to $\frac{1}{24}$ of a grain, while arsenic, believed by some to have a special action on the tissue, is certainly an admirable tonic in the shape of Fowler's solution, five drops at a dose for an adult, or of arsenious acid, $\frac{1}{30}$ of a grain.

The bronchitis is treated by the usual remedies; but at the same time it is of such importance that the stomach should be kept in good condition, and that digestion should not be interfered with, that more than ordinary care is required in the selection of remedies for the bronchitis. A very useful measure in these cases is counter-irritation, which in no way interferes with digestion. Mustard plasters afford in such cases a convenient method of counter-irritation. A mustard plaster can be so prepared that it may be worn continuously without discomfort. The plaster is to be prepared by mixing the mustard and flour, say 1 to 5, with one of equal parts of white of egg and glycerine, instead of with water.

I have mentioned strychnia as a tonic, but it may also be regarded as an expectorant, and I have known secretions in the lungs to be rapidly disposed of by its use. It has also the effect of improving the nutrition of the muscular tissue of the walls of the bronchi, as it has of improving the muscular tissue in its entirety. Full doses should be given. I usually give it in doses of from the thirty-second to the twentieth of a grain, repeated three times a day. This is to be kept up for a long time.

The ammonium carbonate and the ammonium chloride are also useful expectorants where there are abundant secretions. The former is more prompt in its action, and when given alone in-

stead or in combination with syrups, especially senega, is no more apt to derange the stomach than the muriate. It may be given in from 5 to 10 grain doses every three hours, or oftener, if necessary.

The other expectorants, syrup of squill, syrup of senega, and syrup of ipecac, I am slow to use, unless there is some urgent reason for securing a prompt effect. Anything that is relaxing or tends to derange the stomach should not be used. If there is asthma, the relaxing effect of these remedies may be required.

The palliative treatment constitutes an important part of the treatment of these cases. This will, of course, depend to a large extent on the nature of the complication. I have already stated that asthma, *i. e.*, a spasmodic contraction of the bronchial tubules, is one of the most serious and frequent complications of emphysema. While there are certain physical signs significant of emphysema, which consist in feeble inspiratory murmur and prolonged feeble expiratory sound, these are in the majority of cases overshadowed by those of the complication which is present, bronchitis or asthma. You will recollect that in ausculating the chest of one of the patients, we found numerous sonorous and sibillant rales. They can be produced only when there is an abnormal relation between the air entering the lungs and the calibre of the tubules through which it passes. This may be caused in two ways—one by a thickening of the mucous membrane of the tube from inflammation, the other by a narrowing of its calibre from spasmodic contraction. In the present case it is hardly correct to speak of this complication as asthma. This man, however, has attacks in which he is much worse than at present, and has greater difficulty in breathing. These temporary attacks of asthma of course require treatment. I know of no more efficient way of breaking up an attack of asthma, than the hypodermic injection of $\frac{1}{4}$ of a grain of morphia with the $\frac{1}{120}$ of a grain of atropia. This will usually relieve the paroxysm almost immediately. If relief is not complete, the injection may be repeated every six hours. It is under these circumstances that the various inhalations are employed. The smoke of burning stramonium or tobacco, ether, chloroform, and a large number of other remedies which have the effect of relaxing the spasm, have been used in this way. Of course, in connection with the attacks of asthma, the other remedies of service in relaxing the bronchial tubes, such as belladonna and iodide of potassium, are given. Tincture of belladonna, in doses of ten or fifteen drops, combined with ten grains of iodide of potassium, will often break up so much of this condition as is due to spasmodic contraction of the tubules.

To relieve the constant dyspnœa, a treatment was suggested some years ago by Waldenburg, the usefulness of which is much limited by its unavailability. This is the introduction into the lungs of compressed air and the breathing out into rarified air. It is plain that if compressed air can be introduced into the vesicles that the aeration of the blood will be more perfect, and that if the patient breathe into rarified air, the residual air which it is so difficult to get rid of will be sucked out. This requires a special apparatus, known as Waldenburg's apparatus. We have become acquainted with the effect of breathing compressed air from the experience of persons in diving-bells. It slows the pulse and increases the force of the heart's beat, and it slows the respirations while it increases their efficiency. Under these circumstances the blood is more thoroughly aerated, and the embarrassment of respiration is diminished. Breathing into rarified air more completely empties the lungs, the blood rushes in more thoroughly, and is better aerated. Sometimes these patients are benefited by going to high altitudes, while at other times the condition is aggravated. The symptoms in all cases are aggravated at first, but in those which are benefited the increased dyspnœa is gradually diminished. Where relief ensues, it may be ascribed to a more complete emptying of the air vesicles.

If such measures can be employed and the patient kept from having fresh attacks of the affections which have caused the emphysema, he can be kept in comparative comfort; but if he is necessarily exposed to bad weather and subjected to frequent attacks of bronchitis, there is not much relief to be afforded. It is for this reason that these patients always get better when they come into a hospital, where they are housed, receive good food, and are protected from exposure. They improve and leave the institution, but returning to their old habits, again catch cold and come back to the hospital. One of these patients has been discharged and readmitted some seven or eight times.

Medical Societies.

CHICAGO GYNECOLOGICAL SOCIETY.

Regular meeting, December 19, 1884. The President, Dr. H. P. Merriman, in the chair.

Dr. W. H. Byford read a paper entitled

A Case of Mural Pregnancy.

The history of the case was obscure. The patient, twenty-eight years old, married seven years, had one child, six years old. She supposed she became pregnant, for the second time, in February, 1883. In April, she became fatigued and had hemorrhages, which continued until May 9—about four weeks.

October 14, a discharge of yellow fluid, about one gallon in quantity, occurred. A putrescent, sero-sanguineous discharge followed, continuing three months.

January, 1884, a large brownish mass, with very fœtid odor, was expelled. After this event menstruation occurred until July.

In May, she was quite large, and had bearing-down pains. She entered the hospital October 6, 1884. She was tapped October 18, and about four quarts of thick, tenacious fluid, resembling the fluid of an ovarian cyst, were removed. This fluid coagulated on the addition of nitric acid and on boiling. Assisted by Dr. R. Tilley, a microscopical examination was made, with negative results. The "Drysdale" cell was not found. Laparotomy was performed, and a fœtus with pla-

centa was removed without hemorrhage or difficulty. In order to secure perfect drainage, it was considered best to remove the uterus. The operation was performed on October 30. The patient did not react, but died within twenty-four hours. Prior to the operation, the patient was extremely reduced by her protracted sufferings. Dr. Byford, in a similar case, at the present time, would elect the vaginal operation. The specimens removed from the woman were exhibited as supporting the diagnosis of mural pregnancy.

This was the second case of mural pregnancy that had come under the reader's observation within a period of five years. The first case was reported to the Chicago Gynecological Society some time ago. The patient was in labor and moribund when Dr. Byford saw her. She had been in labor until exhausted. There was no difficulty in making a diagnosis. The head was low down in the pelvis, almost on the perineum. The *os uteri* was well nigh inaccessible behind and above the symphysis. The body of the uterus, somewhat enlarged, could be felt in the lower and anterior part of the abdomen, attached to the tumor containing the fœtus. The fœtus could be felt through the abdominal walls, surrounded by a thick involucrum, apparently as thick as the uterine walls. Fœtal extremities could be distinguished. When dissected, the sac, in which the fœtus was contained, was found to consist of a thick layer of muscular fibres. These fibres were directly continuous with those of the uterus. The tubes and ovaries lay on either side of the lower portion of the sac. The fecundated ovum had made its way down the tube, become lodged in a diverticulum in the uterine wall, and was gradually extended into the cavity of the abdomen. The fœtus was thus developed within the uterus, though not within the uterine cavity. The resemblance to normal pregnancy is great in the presentation and position of the fœtus, deep down in the pelvic cavity, behind the vagina. The head, in this case, was fixed by the concentric contraction of the uterine fibres, by which it was surrounded, and could be easily outlined as it lay there covered by the posterior vaginal wall.

The specimen presented is much less perfect than the one described, because of the numerous effects wrought upon it during the great length of time it remained in the maternal body, and the mutilation consequent upon enucleation.

The treatment of these cases ought to be considered apart from that of extra-uterine pregnancy at term. It is always a matter for special consideration in connection with each case as it presents itself, whether or no the removal of the fœtus at term in extra-uterine gestation should be attempted. The dangers of laparotomy are greatly increased by the inability to remove the placenta. The surface to which it is attached has no contractile power, so that the divided vessels are left patulous. If hemorrhage does not immediately prove fatal, the blood is a source of sepsis that must almost certainly destroy the patient. Laparotomy would more likely prove successful if performed some days after the death of the child. In these cases of ectopic or interstitial uterine pregnancy, the fœtus may be easily removed through the vagina. An incision made through the posterior vaginal wall would completely uncover the presenting part and enable one to apply the forceps, or attack it with the perforator and crotchet, as in ordinary labor. After the removal of the fœtus the placenta should be allowed to separate spontaneously.

Since writing this report, Dr. Byford has seen a case, reported in the *Annales de Gynecologie*, July, 1884, occurring in the practice of Dr. Matheson, of England, illustrative of the execution of this plan. The case was reported to the London Obstetrical Society, under the title, "Extra-uterine Pregnancy, the Extraction of a Living Fœtus through the Vagina." The child was slightly asphyxiated, but survived. A sponge, saturated with perchloride or iron, was introduced into the sac after removal of the placenta. The mother recovered. It would seem that the author did not expect his case to be one of interstitial pregnancy. During the discussion that followed only one of those present expressed the opinion that it was of that variety. Mr. Griffith thought it was either interstitial pregnancy or one in which the fœtus was developed in one portion of a double uterus.

DISCUSSION.

Dr. Edward Warren Sawyer thought that interstitial pregnancy meant the development of the ovum in the uterine portion of one of the tubes. In Dr. Byford's case the uterine portion of the tubes was not involved. It reminded him of a case he had seen near Denver. In this case, a secondary uterus, with muscular walls, had been developed, but as the tubes were not involved, he did not feel justified in designating the case one of interstitial pregnancy.

Dr. D. T. Nelson said with reference to the treatment of the placenta, that Dr. Byford's advice was that usually recommended in the text books. The placenta should be left alone in those cases in which the walls of the secondary uterus were not muscular. He had seen a case in the museum of the Chicago Medical College in which no muscular fibre could be detected in the walls. When the walls of the adventitious uterus were muscular it was questionable whether or no the placenta should be left alone. If the placenta is removed, there is danger of hemorrhage; if the placenta remains, there is danger of sepsis. While there was reason to suppose that contractions of the adventitious uterus would check hemorrhage, he thought the placenta should be removed. He had had no experience in these cases.

Dr. E. C. Dudley replied to Dr. Nelson. Women, in cases of extra-uterine pregnancy, in which the placenta has been allowed to remain, do not die of sepsis. He had seen two or three cases in which the sac had been united to the abdominal incision. Whenever evidence of sepsis occurred, the sac was washed out, and the temperature immediately fell to the normal. The placenta under these circumstances is spontaneously eliminated in about three weeks.

It requires phenomenal powers of diagnosis to tell in the concrete case whether or no the sac had sufficient muscular fibres to prevent hemorrhage. The placenta should be permitted to remain within the sac.

Dr. J. H. Etheridge thought that if, on microscopical examination, it was found that the mus-

cular fibres of the normal uterus were continuous with those of the adventitious uterus, the case was one of mural pregnancy. In cases of abdominal pregnancy, there was a line of demarcation between the normal and adventitious uterus.

Dr. A. Reeves Jackson thought the members of the society were greatly indebted to Professor Byford for the presentation of such an interesting specimen. He thought, however, with Dr. Sawyer, that the results of the anatomical investigation did not support the author's diagnosis. The uterine portions of the tubes were not involved. So valuable a specimen deserved very close microscopical and macroscopical examination. It ought to be referred to a competent pathological anatomist.

Dr. John Bartlett thought the ovum had not passed through the tube, but had been developed in the broad ligament beneath the peritoneum, and had, in this manner, derived muscular fibres from the uterus.

Dr. W. W. Jaggard referred to the fact that next to ovarian pregnancy, interstitial pregnancy was of most infrequent occurrence. Up to the present time about thirty cases in regard to which the diagnosis was positive have been reported. Interstitial or mural pregnancy included other sites of development than the uterine portions of the tubes. Dr. Gilbert's case, reported in the *Boston Medical and Surgical Journal*, March 3, 1877, and alluded to by Professor Lusk in his treatise on midwifery, was a case in point. The ovum in this case was developed in what seemed to be a bifurcation of the fallopian tube. In Dr. Byford's case, the tubo-uterine orifices were not involved. The sac was extrinsic to the uterine walls. It was probably a case of abdominal pregnancy in which the ovum became attached to the posterior uterine wall, and derived muscular fibres from its loeality. The fact that a continuity of muscular fibres from the normal uterus to the adventitious uterus might be ascertained upon microscopical examination, would prove nothing as to the nature of the pregnancy. Dr. Byford's case resembled that of Jauverin, in which the ovum lodged on the posterior uterine wall, and developed in this situation, involving the posterior wall in its sac. The specimen was worthy of more exact investigation, and should be placed in the hands of a competent pathological anatomist.

Dr. Sawyer said that abdominal pregnancy, with location of ovum on posterior uterine wall, was not at all improbable. He then referred to Bischoff's and Leopold's observations and experiments with relation to the "external wandering over of the egg." Beigel had ridiculed this idea. It was like a blind man introduced into a large, empty room, with a thread in his hand, seeking to find and thread the eye of a needle located in some indefinite quarter of the room. Notwithstanding the sarcasm, the fact of the external wandering over of the egg was a matter of positive knowledge. The egg may pass from one ovary to the opposite fallopian tube through the abdominal cavity. He thought the specimen exhibited was one of abdominal pregnancy.

Dr. Dudley thought the fact of the external wandering over of the egg was not disputed at the present time. Playfair in his treatise on midwifery gave a clear exposition of the subject.

Dr. Charles Warrington Earle said that the fact of external wandering over of the egg was fully recognized twelve years ago.

Dr. Sawyer said the ovum in abdominal pregnancy might be attached to the posterior wall of the uterus, the mesentery, under surface of the liver, or to other viscera.

Dr. Nelson made the remark that in both of the cases cited by Dr. Byford, *deciduæ* had been cast off by the *uterus*.

Dr. Jackson said that Fränkel was of the opinion that the formation and extension of a *decidua* was a constant occurrence in extra-uterine pregnancy. It was pathognomonic of the condition.

Dr. W. H. Byford was not surprised that certain members did not agree with him in his diagnosis. He thought that in the first case the fecundated ovum passed through the tube, but had found some diverticulum in the uterine cavity, and had passed into the posterior wall, and developed in this region, pushing the wall before it. Some of the reasons for this position were as follows:

The muscular elements of the sac were directly continuous with the uterine muscle. He did not believe that such a muscular sac could develop adventitiously in the abdominal cavity. He had seen cases of abdominal pregnancy, with no muscular fibres in the sac. The head presentation, down deep in the pelvic cavity, in the direction of the resultant of the forces developed by uterine contractions, supported his view of the case.

It is not necessary for the production of mural pregnancy that the tubes be involved. He thought there was much in the remarks of Dr. Nelson and Dr. Dudley. In cases in which there was sufficient contractility, it was best to remove the placenta. Even under these circumstances, it was not absolutely necessary. There was no danger in allowing the placenta to remain.

Finally, he was very positively of the belief that the two cases referred to in his paper were examples of mural pregnancy. The peritoneum was a boundary line between mural and abdominal or peritoneal pregnancies.

Dr. Sawyer asked the question, "Is the peritoneum a boundary line of importance in the macroscopical or microscopical differential diagnosis between abdominal and mural pregnancies?"

Dr. Jaggard, in reply, said that the peritoneum was no barrier. What was the peritoneum? Dr. Etheridge, in an article on "Chronic Adhesive Perimetritis," published in a recent number of the *Chicago Medical Journal and Examiner*, had ably sketched the anatomy of this membrane. It was developed out of connective tissue, according to Rindfleisch and other distinguished anatomists. It offered absolutely no barrier to the attachment of the ovum to the posterior uterine wall, and its development in this situation, with the derivation of muscular elements from the normal uterus.

On motion, Drs. Byford, Merriman, and Jaggard were appointed a committee to select a competent pathological anatomist, who did not belong to the Society, to examine the specimen and report at the next regular meeting. It was specified in the resolution that the *pathologist should be amply paid for the labor.*

Dr. Etheridge then exhibited a placenta with calcareous deposits. The placenta was removed from the body of a woman, pregnant for the first time, who had probably carried the fœtus 292 days. The calcareous deposit was probably the result of fatty metamorphosis of the upper layers of the *decidua serofina*.

Dr. Sawyer said the placenta was interesting, but not uncommon. It has been erroneously believed that such *placentæ* are of syphilitic origin. He thought the connection with prolonged gestation was established.

Dr. Dudley referred to the calcareous deposit in the wall of the arteries supplying an ovarian cyst, which he had removed some years previously.

Dr. Jackson related the history of a case in which he had removed a mass of calcium carbonate situated in the recto-vaginal septum, one and one-half inches from the vulvo-vaginal orifice. There was no fatty metamorphosis in this case.

Dr. Earle thought there was an unreasonable tendency to ascribe such cases to the effects of syphilis. Hydatidiform degeneration of the chorionic villi and *hydrops amnii* received a similar erroneous etiology.

Dr. Etheridge said that the deposits were composed of phosphate and carbonate of calcium. These salts had an affinity for albumens, and fatty acids present in the cotyledons. Similar calcareous deposits were met with in fibroids, thrombi, encysted trichinæ, and in the lithopædia of extra-uterine pregnancy.

Dr. W. H. Byford thought the connection between prolonged gestation and calcareous deposits in the placenta was established. He thought that Dr. Etheridge would find on microscopical examination that the changes had occurred exclusively within the vessel walls.

The Society then adjourned, to meet on the third Friday evening in January at the residence of Dr. E. C. Dudley, No. 2317 Indiana avenue, at eight o'clock.

The business of the next meeting will consist of:

1. Report of pathologist, Dr. Christian Feager, on Dr. Byford's specimen.
2. Exhibition of specimens from a double ovariotomy, by Dr. E. C. Dudley.
3. Discussion of certain methods by which the second stage of labor may be rendered easy, by Dr. Henry F. Byford.

W. W. Jaggard, M. D., *Editor.*

2330 *Indiana Avenue, December* 22, 1884.

Hydrochlorate of Cocaine in the Nose and Throat.

Dr. E. Fletcher Ingals thus writes in the *Jour. Am. Med. Ass.*, November 22, 1884:

After having noticed the statement by M. Du Cazal, that tincture of coca would relieve painful affections of the throat, I made several trials of the remedy, but failed to get satisfactory results: and since the publicaiion of Dr. Agnew's report on the hydrochlorate ot cocaine, being unabe to obtain any of the latter, I have made trials of a strong solution of the extract of coca, and also of citrate of caffeine, which, from its close resemblance to cocaine, I hoped might produce similar local effects; but in both I was completely disappointed.

I was unable to obtain any of the hydrochlorate of cocaine until the 13th of this month, when I received a 2 per cent. solution from New York. My first trial was in a healthy subject, who, however, had a very sensitive Schneiderian mucous membrane. I ascertained by experiment that, with the moderate pressure applied, only about 10 per cent. of a spray applied to the nostrils would be lost. I then applied the solution in the left nasal cavity, first by a spray, and afterward by a hypodermic syringe fitted with a long probe-like nozzle. I applied in this case 26 minims of the solution during the space of forty-five minutes, from two to four minims being applied at intervals of three to six minutes, with the following result: Fourteen minutes after the first application there was a decided loss of sensibility, though pressure caused pain. In thirty minutes anæsthesia was nearly perfect, 18 minims having been used, and in forty minutes sensitiveness was returning. In forty-five minutes the membrane was quite sensitive, and in fifty minutes sensibility was almost normal, notwithstanding the continuous use of the cocaine. The soreness caused by the probing caused considerable pain, which radiated to the eyes and side of the head, and lasted for three or four hours.

Case 2. Male, aged 19. Naso-pharyngeal fibroma. In this case a portion of the fibrous growth, which was attached to the side of the posterior border of the septum, had to be cauterized.

Two previous cauterizations had given the patient very severe pain, which "shot through his whole head." The nasal cavity was first washed out with Dobell's solution, and afterward with a weak solution of hydrochloric acid. It was then dried by absorbent cotton, and the two per cent. solution was applied with the syringe to the part to be cauterized.

I used thirty minims during thirty-six minutes, in quantities of four to five minims every five minutes, with the following results: In seven minutes sensitiveness was considerably diminished. In fourteen minutes sensitiveness greater than before. Thirty-six minutes after the first application, half a drachm of the two per cent. solution having been applied, he could feel the probe, but it caused no pain excepting in one spot. I then applied the cautery thoroughly about three times as long as on previous sittings, causing very little pain—he thought about one-tenth as much as formerly.

Case 3. Male, aged 62. At two previous sittings I had removed from this gentleman's nares large mucous polypi, but to-day I found the base of one springing from the middle meatus of the right side. I dried the parts with cotton, and during ten minutes applied ten minims of a two per cent. solution as thoroughly as possible immediately about the polypus. Nineteen minutes after the first application, I removed the polypus with snare and forceps, and then cauterized its base with the galvano-cautery. He said the pain was very slight, not more than one-tenth what he had experienced from previous operations of the same character. He was exceedingly pleased at the result.

Case 4. Male, aged 34. Nasal polypi, with exceedingly sensitive Schneiderian mucous membrane. Applied first five minims of a two per cent. solution, five minutes later four minims more. Six minutes later parts not sensitive to probe. Cauterized base of polypus in middle meatus with galvano-cautery, with about one-fifteenth the pain he had experienced from a similar operation a week previously.

Case 5. Male, aged 29. Hypertrophic catarrh. This patient came from Iowa, and as he wished to return the same evening, I desired to relieve him as completely as possible at one sitting. To the left naris, which was very sensitive when touched with the probe, the two per cent. solution was applied as in the preceding experiments, in quantities of one to four minims at intervals of one to four minutes, with the following results: There was some numbness at the end of seven minutes, and very little sensitiveness at the end of eleven minutes, but eight minutes later, notwithstanding the continual use of the drug, the sensitiveness was about the same. I then transfixed the lower turbinated body, and applied the snare without pain, though he felt it; but when the snare was tightened, considerable pain was experienced. Three minutes later the sensitiveness of the part was about one-third that of the side not treated.

While doing this operation I received word that the cocaine ordered from Germany had arrived. I immediately sent for it, and had a four per cent. solution made.

Second trial in case 5. An hour and a half later I applied the four per cent. solution to the right naris. The cavity was first dried with cotton and twelve minims applied in quantities of one to two minims at intervals of two or three minutes during twenty-three minutes, at the end of which time he said the sensitiveness was more than at first, though it had been much obtunded ten minutes earlier. I then swabbed out the naris carefully and applied four minims more of the solution. Five minutes later I cauterized the inferior turbinated body thoroughly, causing about one-fourth the amount of pain ordinarily experienced from similar though much shorter operations.

Case 6. Female, aged 33. Anosmia dependent partially on submucous thickening of the upper part of the septum, which was swollen so as to protrude three-sixteenths of an inch. I first dried the mucous membrane with a jet of compressed air and then applied the four per cent. solution by means of the syringe, dropping upon the surface half a minim every half minute for three minutes, and afterward every three minutes until ten minutes had elapsed, when I found anæsthesia of the part complete. I then cauterized the swollen tissue thoroughly, passing the hot wire twice through its base without causing the slightest pain. A similar operation in the opposite naris had previously given this patient severe pain.

Case 7. Male, aged 21. Deflection of the septum with exostosis forming a spur one and three-fourths inches long, projecting a fourth of an inch from the normal plane of the septum and decreasing the normal calibre of the air-passage eighty per cent. The nasal mucous membrane was unusually sensitive. I applied a loose pledget of absorbent cotton below the spur, and having dried the membrane with the jet of air, repeatedly dropped upon the upper surface of the spur, from one end to the other, a four per cent. solution; averaging half a minim every half minute for the first six minutes. Some of this ran down into the cotton below the spur, but at the end of several minutes from the first application, when the upper surface was completely benumbed, I found the lower still acutely sensitive. I then removed the cotton and dried the passage with the air jet and applied more of the solution in the same manner as before, both above and below the spur. Twelve minutes after the first application, having used eight minims of the solution, I found the parts to be operated upon completely anæsthetized. I then sawed off the spur (this part of the operation requiring about four minutes), without causing the slightest pain. In removing the detached bone, some pain was caused by touching the outer wall of the naris, which I had not attempted to anæsthetize. Twenty minutes after the first application, sensibility was rapidly returning, and five minutes later the parts were again sensitive to the probe.

Case 8. Mrs. W. Small cystic tumor at the lower part of the left side of the base of the tongue, about half an inch below the tonsil, with several diseased follicles in the tonsil filled with their desiccated secretions. I wished to destroy part of these with the galvano-cautery. But the patient so feared pain that I attempted to benumb the parts by injecting on the upper part of the tonsil the four per cent. solution, which trickled down so that I supposed the membrane over the cyst would be reached. Five minims were used in the course of five minutes, the mouth being kept open. Three minutes later the patient complained of something being lodged in her throat which made her retch and nearly caused vomiting; this sensation, which was due to the benumbing effects of the cocaine, lasted about five minutes. As soon as the tendency to retch ceased, I destroyed the cyst with the galvano-cautery, but the anæsthetic effect of the cocaine seemed to have entirely disappeared.

Case 9. Male, aged 31. Hypertrophic catarrh. Dried the parts with the blast of air, and then applied the four per cent. solution of hydrochlorate of cocaine to the inferior turbinated body of the right side, eleven minims in thirteen minutes, from one-half to one minim every minute.

In this case, as in others of hypertrophic catarrh, the solution caused the swelling to almost completely disappear by the time the anæsthesia was complete.

The turbinated body was cauterized thoroughly without pain. The patient complained of a sense of dizziness and slight dyspnœa for ten minutes, but had no unpleasant sensations afterward,

Case 10. A little girl, aged 6. Adhesion of turbinated body to septum, causing stenosis of right naris.

Applied the solution as in the last case, excepting that half of it was used with the atomizer and only eight minims were employed.

In fourteen minutes anæsthesia was complete, and the adhesions were broken down without pain.

Second application in case 2. On the patient's next visit to my office, I applied the four per cent. solution to the naso-pharynx, which still contained quite a large mass of the fibrous growth. He has always complained bitterly on any manipulation of the part; but after having used ten minims by the atomizer, a minim every minute, the surface was anæsthetized; however, by the probe I found that deeper parts were still sensitive.

I then introduced, by means of the probe-pointed syringe nozzle, six minims more in various places where the contact of the probe caused pain. In twenty-five minutes the parts were so thoroughly anæsthetized that I commenced the operation of removing the mass with cutting forceps. The operation lasted about ten minutes, and gave no pain excepting in one small spot, though he said he felt the instrument whenever introduced or moved.

From my experience with cases one to five inclusive, I concluded when the solution is applied in the naris every four or five minutes a partial anæsthesia occurs in ten or fifteen minutes after the first application, and that it is followed, like the first effects of ether when given slowly, by a period of two or three minutes of exalted sensibility, and that if its use be continued (possibly without further use) the maximum effects of the anæsthetic are quickly reached. The anæsthesia disappears in about five or ten minutes. These cases also suggest the query, whether, after a short time (thirty to forty-five minutes) it might not be very difficult to maintain anæsthesia even by repeated applications? These same cases also convinced me that a two per cent. solution is not ordinarily strong enough for use in the nose. From all the experiments, I conclude also that the drug does not act satisfactorily unless the mucous membrane is free from secretions; and wiping out the nasal cavity with cotton, though it dries it for a few seconds, excites excessive secretion directly afterward, therefore drying may be much better accomplished by the jet of air.

These cases, as far as they go, also suggest the advisability of overcoming the sensitiveness as quickly as possible by frequent applications, which keep the surface constantly bathed in the solution. When used in the fauces, it was entirely unsatisfactory in one case, but I attribute this partly to the particular patient and partly to the imperfect application of the solution. Dr. Solis Cohen's experiments with it in the larynx have not been satisfactory, but we will doubtless soon learn how to obtain better results from its use in the fauces and larynx.

One of the remarkable properties of this drug, which I observed when I first applied it to the swollen mucous membrane of the turbinated bodies, is that of causing prompt and rigid contraction of these tissues. This action has proven to be uniform, and I have learned by experiment that the contraction may continue several hours. This property will render the cocaine almost a specific for the relief of the "stuffing up" of the nose which occurs in acute colds, hypertrophic catarrh, and hay asthma, as well as for the throat deafness, which results from swelling of the mucous membrane lining the Eustachian tubes.

Voluminous Enemata of Nitrate of Silver in Chronic Dysentery.

Before the Clinical Society of London, November 14, 1884, Dr. Stephen Mackenzie read a paper on this subject. He alluded to a former series of cases he had brought before another society, and stated that extended experience had strengthened his belief in the value of large enemata of nitrate of silver in the treatment of cases of chronic dysentery or dysenteric diarrhœa. The mode of procedure he adopted was as follows: The quantity of nitrate of silver to be used was dissolved in three pints of tepid water in a Leiter's irrigating funnel, which was connected by India-rubber tubing with an œsophageal tube with lateral openings. The patient was brought to the edge of the bed, and made to lie on his left side, with his hips well raised by a hard pillow. The terminal tube, well oiled, was passed about eight or ten inches into the rectum, and the fluid allowed to force its way into the bowel by gravitation. The injection rarely caused much pain, and often none. It usually promptly returned; but, when long retained, it was advisable to inject chloride of sodium, to prevent absorption of the silver salt. Various strengths had been used, from thirty to ninety grains to three pints of water; but usually one drachm of nitrate of silver was employed. The treatment was based on the view that, whatever the nature of dysentery, whether constitutional or local, in the first instance, the later effects were due to inflammation or ulceration of the colon, which was most effectually treated, as similar conditions elsewhere, by topical measures. Sometimes one, sometimes two, injections were required, and in some cases numerous injections were necessary; but in all the cases thus treated, many of which had been unsuccessfully treated in other ways previously, the disease had been cured. In most cases other treatment was suspended, but in some, Dover's powder or perchloride of iron, which had been previously administered, was continued or subsequently prescribed. The cases narrated were these: 1. One in which the disease had lasted several years on and off; two injections were used, and the case was cured in six weeks. 2. Second attack, duration uncertain; four injections used; cured in five weeks. 3. Duration two months; two injections used; cured in three weeks and a-half. 4. Duration five years; one injection used; cured in three weeks. 5. Duration eighteen months; two injections used; cured of dysenteric symptoms, but remaining under treatment for diabetes. 6. Duration fourteen months; one injection used; cured in seven weeks. The treatment, which

laid no claim to novelty, was brought forward to elicit the experience of others who had tried it, or to induce others to employ it in suitable cases.

Dr. Carrington gave as a reason for doubting the probability of Dr. Mackenzie's results being repeated, his own unsuccessful employment of the remedy used; but, in view of the favorable termination of the recorded cases, he had determined to give the method a new trial.

The President pointed out that the mode of treatment adopted did not originate with Dr. Mackenzie, and that that gentleman had carefully insisted on this fact.

Dr. Cullimore asked for information as to the duration of allied cases of disease treated in the hospital by other methods than that practiced by Dr. Mackenzie, and also whether the author of the paper was inclined to confine such treatment to cases of rectal dysentery, or to apply it to others as well. He commented on the fact that most of the cases recorded were those of sailors, and suggested that the favorable result might be, in great part, due to the improved surroundings of the patients, the physiological rest and appropriate diet, etc., afforded in hospital, as compared with the depressing surroundings of an existence on board ship. In his own experience of the treatment, he found that pain was produced, in one case, on the injection of two pints of water, holding forty grains of silver-nitrate in solution. In another case of dysentery, due to famine, he injected half a pint of water containing iodoform, but without effecting any good result. Opium and krameria were, in his opinion, the most useful remedies in this class of cases.

Dr. Dyce Duckworth had only resorted to the treatment by injection of silver-nitrate solution once; but one injection was made, and the result was not satisfactory. It should be remembered, he urged, that all so-called cases of dysentery were not alike. The disease varied much in different individuals, as was the case also with many other forms of disease, and this fact had not been sufficiently recognized by writers on tropical affections.

Dr. B. O'Connor asked how long a time had elapsed between the adoption of the treatment and the present.

Dr. S. Mackenzie said he had purposely used the term chronic dysentery, or dysenteric diarrhœa, in writing his paper, as being most appropriate to the kind of cases under discussion, these being characterized by teasing diarrhœa and considerable constitutional disturbance. In a previous paper, he had explained that the physicians at the Seamen's Hospital had spoken hopelessly of all kinds of treatment; but at the London Hospital, greater opportunities existed for making observations in this respect than at any similar institution, with the exception of the one just named; and in all his own cases, the effects of rest, opium, etc., had been tried in vain before resort was had to the injection-method of treatment. He alleged that rebellious cases were cured by the enema, and that it was, therefore, a resource to be adopted whenever the ordinary remedies failed. He himself would adopt it in ordinarily severe cases at the outset of treatment. He had no definite statement to make as to the permanence of the cure, the class of patients concerned being the most difficult of any to keep under observation; but, in this connection, it might be interesting to the Society to know that one patient cured by him had returned twelve months after being discharged, not on his own account, he being still well, but to solicit Dr. Mackenzie's good offices in behalf of a friend who was suffering, as he had been, from chronic dysentery.

Russian Baths.

In order to determine the influence of daily Russian steam baths on the healthy system, Dr. V. V. Godlevsky (*St. Petersburg Inaugural Dissertation*, 1883) made a series of careful observations on two quite sound and strong men, who, for the first ten days, daily took a simple vapor-bath, and then, after an interval of another ten days, daily took a vapor-bath, with rubbing and beating the skin by a *venik* (a bundle of birch twigs with leaves.)

The effects, as enumerated by the author, were as follows:

1. The pulse and respiration considerably increased in frequency.
2. The circumference and expansion of the chest became somewhat larger.
3. The energy of expiration and inspiration decreased.
4. The capacity of the lungs decreased.
5. The axillary and rectal temperature rose.
6. The weight of the body fell considerably.
7. The volume of the limbs increased.
8. The circumference of the belly decreased.
9. The muscular strength of the hands lessened slightly, and that of the feet and abdomen considerably.
10. The daily amount of urine decreased, but its density increased.
11. The excretion of nitrogen was considerably increased, the increase lasting for five days after completing a series of baths.
12. The excretion of phosphoric and sulphuric acids also increased, but less considerably.

The action of baths with the application of a *venik* is more powerful than that of simple vapor-baths.

The author thinks that vapor-baths administered daily for a certain more or less prolonged time may prove useful: 1, as a means of intensifying the process of metamorphosis in tissues; 2, as a powerful revulsive; 3, as a sudorific; 4, as a means of improving the action of the skin.

Accordingly, Russian baths are indicated: (1) in chronic muscular and articular rheumatism, as well as in gout; (2) in secondary and tertiary forms of syphilis; (3) in scrofula; (4) in obesity, and in plethora from overfeeding and sedentary life; (5) in the initial stages of catarrh of the nose, throat, bronchi, lungs, bowels, and bladder; (6) in chronic catarrh of the external auditory meatus (as recommended by Dr. Strom), the pharynx, tonsils, and nose; (7) in chronic inflammation of the spinal cord and its membranes (as recommended by Bartels, Frey, and Heiligenthal), and in hypochondriasis; (8) in chronic congestion of the liver, spleen, stomach, bowels, as well as in the algide stage of cholera; (9) in rheumatic, scrofulous, and syphilitic disease of bones; (10) in intermittent fever (in the stage

of rigor); (11) in apyretic cases of ascites and serous pleuritis, and non-cardiac dropsy; (12) in hydrophobia (Sanjez, Buisson, Turkish baths in hydrophobia were recommended by Dr. R. Neale); (13) possibly, in diabetes, as well as (14) in the cases where the formation of biliary and cystic calculi may be suspected.

The contra-indications for Russian baths are as follows: (1) all rather prolonged acute febrile diseases; (2) tendency to hemorrhage; (3) general weakness and exhaustion after acute diseases; (4) acute affections of the eye and ear; (5) uncompensated diseases of the cardiac valves, fatty degeneration of the heart, arterio-sclerosis of higher degrees, and aneurism; (6) tendency to pulmonary and cerebral congestion, plethora of higher degrees; (7) considerable pulmonary emphysema, phthisis in the last stage; (8) obstinate constipation from atony of the intestines; (9) pregnancy with tendency to abortion; (10) very hot Russian baths are contra-indicated, also, in the cases of old people, and infants.

Emetics in Hysteria.

Dr. Peyton Turner thus writes in the *Texas Courier-Record of Medicine*, November, 1884:

The administration of emetics in hysteria would no doubt be regarded as a rather severe measure by some practitioners, myself for one, were they employed indiscriminately. Obstinate cases, however, present themselves not infrequently, denoted by a recurrence of the convulsions, coma, etc., after restoration to complete consciousness by anti-spasmodics, cold douche, etc., and it is this class of cases in which emetics are especially valuable; in fact, where the usual remedies fail I have been led to believe from experience that the emetic treatment is probably the most efficacious at our command, and more especially when the paroxysms come on after the ingestion of food. No remedy should be extolled as curative without a reasonable trial of its merits, and to give a medicine we know will vomit alike in every case, would be incompatible with a proper course to pursue, and alike injustice to our patients. We know the effect of emesis on the nervous system, and this would probably explain in a nutshell their manner of controlling hysterical convulsions, and cases do sometimes present themselves in which this treatment is not only justifiable but imperative; and to make their usefulness more apparent, I herewith append a succinct report of several cases:

Case 1. I found in a semi-unconscious condition, globus hystericus well-marked, and without delay I gave an emetic, which was followed by free vomiting and a subsidence of all the symptoms. I will presently explain why I gave an emetic in this case.

Case 2. I was called to attend at midnight, and found her in hysterical coma. I managed to get a thimbleful of zinc sulphate down her, and when it began to act, it seemed to restore consciousness and all the normal functions at once, and she forgot to get sick any more that night. This case was a negress.

Case 3. I was called hurriedly to attend a lady at a hotel who was supposed to be dying from the effects of some poison. I diagnosed hysteria. She was having violent convulsions, alternating with coma. In this case I used anti-spasmodics freely without any signal benefit. I then tried the cold douche, which seemed to have a happy effect in ten minutes, but was only momentary; the convulsions would recur with such violence that four men could not hold her. I then tried fifteen grains of zinc sulphate, free vomiting ensued, and a cure was at once effected.

Case 4th was in a similar condition as the last, the usual remedies proved futile in like manner; the sulphate was administered with precisely the same results.

These four cases are the only ones in which I have given emetics, as I always try the common remedies first, and I find them successful in a large majority of the cases.

The first case here mentioned happened in my practice years ago, when I was a *kid*, and was practicing at that time in Louisville, Ky. The woman's husband came after me (probably because he could not get another doctor) in a great hurry, saying for God's sake to come as quick as I could, as his wife was about to strangulate. This thew me completely off my guard, and as I had just "hung out my shingle," I was more than anxious to go with him, and was ready at a moment's notice. It was about four blocks to his house, and sure enough I found the lady as I thought strangling to death, and grabbing at her throat as if she wanted to tear the trachea out by the roots. It scared me within an inch of my life; she was moaning terribly, and I studied what in the —— could be the matter with her. I tried to look very knowing, and her husband partly relieved my embarrassment by telling me she *ate an apple the day before*, and maybe the core had lodged in her throat. I examined her throat, but could see no *core*, not even a red spot that I could tell him was a *pathological condition of the copillary blood vessels*, but I told him the core was further down than I could see, and that an emetic would be the most scientific treatment; so I prescribed zinc sulphate, and, after explaining to him how it would produce, *inverted peristaltic œsophageal action*, took my departure, after assuring him that I would return about the time this action was taking place. I went back to my office as quick as I could (I almost ran when out of sight), got my medical works, and glanced hurriedly over the articles on *foreign bodies in the air passages*, but they did not seem to fit the case. My time being up, I went back, and found the inverted action of the cardia and œsophagus taking place as I told him it would, and after free emesis the patient was all right. A little girl stepped up to the bed and said, "Lor' me! Ma's got so she can talk since the doctor come."

These little incidents in mistaken diagnosis serve to remove the motes from our eyes, banish self-conceit, enliven us to the responsibility of our profession, substitute a further desire for investigation and knowledge, and we should ever be ready and willing to acknowledge the corn and be profited thereby.

—It is said that the application of a decoction of valerian root, an ounce to the pint, often relieves completely the pain of contused wounds.

Reviews and Book Notices.

BOOK NOTICES.

Surgical Handicraft: A Manual of Surgical Manipulations, Minor Surgery, and Other Matters Connected with the Work of House Surgeons and Surgical Dressers. By Walter Pye, F. R. C. S. 8vo., pp. 544. Price, $5.00. P. Blakiston Son, & Co., 1884.

There is a certain degree of novelty in the plan of this work which will recommend it to a wide circle of readers. Although written for an English public, and, in some respects, not quite suited to the surgical conditions of American life, the hints and instruction it gives are good everywhere.

The author begins with a section on the arrest of hemorrhage; this is followed by sections on apparatus for restraint and support, such as splints, bandages, etc.; on the immediate and permanent treatment of fractures; on the dressing of burns, wounds, ulcers, etc.; on cases requiring long mechanical treatment, as hip and spinal diseases; on surgical emergencies, as hernia, shock, drowning, and the like; on the administration of anæsthetics, and on pulling teeth, and such minor operations. A formulary and a good index close the volume.

It will be seen from this epitome of the contents that this is a very handy book to have on one's shelves, containing a great deal of just such information as the young physician likes to have at his fingers' ends, and a description of the latest and best methods of doing familiar things, that the old physician can profit by learning. It is reasonably well illustrated, and the mechanical preparation of the book is fairly done.

A Theoretical and Practical Treatise on Hemorrhoidal Disease, Giving Its History, Nature, Causes, Pathology, Diagnosis, and Treatment. By William Bodenhammer, M. D. 8vo., pp. 297. Wm. Wood & Co., New York, 1884.

There is, as the author says, room for a monograph on piles, but for a treatise of three hundred large octavo pages, there scarcely is room. A limit should be drawn to the size of a monograph. If the whole of medicine and surgery were written up on this scale, a physician would have time for nothing but reading. He does not make his living by reading, however, and it were well for both writers and publishers to remember this.

Apart from its needless prolixity, the work of Dr. Bodenhammer is a good one. It goes at great length into the history of the complaint, traces it from the dawn of history to the present day, explains the etymology of the name, gives a host of opinions of every debated subject with reference to it, and is full on the treatment.

For the young physician who has plenty of time on his hands and inclines to make a prolonged study of hemorrhoids, this would prove a satisfactory book. The "busy practitioner" will find life too short to undertake monographs of this magnitude.

Transactions of the Michigan State Medical Society for 1884. Lansing, Mich., 1884.

This is a neatly-printed pamphlet of about 200 pages, containing the usual proceedings and a number of original articles. Many of these are of marked merit, and in looking over them we cannot but regret that they should be buried in a volume of proceedings quite sure not to be seen but by a few hundred at most of the 50,000 reading medical men in the United States.

The subjects of the papers are: "Nasal and Aural Catarrh," "Chronic Inflammation of the Ear," "Granular Lids," "Placenta Previa," "Diphtheria," "Uterine Displacements," "Dysmenorrhœa," "Prostatic Hypertrophy," and similar topics of general and immediate interest to the practicing physician.

The number is one every way creditable to the Society and to the profession of Michigan.

Fourth Annual Report of the State Board of Health of New York. 8vo., pp. 448. Albany, 1884.

The increased attention to sanitary science is a cheering sign of modern legislation. Every state in the Union should have a well-organized and active Board of Health, which should publish every year a series of local investigations, such as are in the volume before us. It contains a number of reports on outbreaks of diphtheria, malarial fever, enteric fever, rubeola, typhus, and on milk, kerosene oil, glucose, pond nuisances, drainage, etc., all of them topics which immediately interest the lives, health, and comfort of thousands of citizens. The time will come when the gross neglect of such matters which now prevails in this and other States will be recorded in history as a proof of the low and semi-barbarous condition of our pretended civilization.

The New York report will be found a very instructive one by hygienists. It is embellished with maps and diagrams. Its statistical tables are full, and several illustrations from the microscopical work of the Board are inserted.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

CAPITAL PUNISHMENT.

We took occasion some time since to note that popular opinion in England is setting strongly against capital punishment. The leading journals and the leading minds are asking whether the purpose which it is designed to fulfill, namely, that of preventing crime, is being accomplished by it; and they seem inclined to hold the negative view, and to regard capital punishment as an unsatisfactory institution, while the *London Lancet* even goes so far as to hold up to ridicule the idea of a great nation like England *strangling* its malefactors. The advisability of capital punishment has occupied the serious attention of some of the greatest men that have ever lived, and arguments *pro* and *con* have not been wanting.

Judging from the experience of the past few years in this city, we would be inclined to think that popular opinion is setting against hanging as a punishment for crime, and that we are commencing to look upon capital punishment as but little, if any, better than judicial murder. Of course, we cannot afford, in the interests of civilization, to allow men to go free who are capable of killing their fellow-creatures; but whether we have the right to kill in turn, seems to be a question that is open to argument.

The fact that we have now in our prison a condemned murderer, who has been incarcerated for five years, in whose case the Supreme Court refused to interfere, and who has just now, after these long years of waiting, been refused clemency by the Pardon Board, is an argument tending to show that those presumably intelligent men who have charge of the administration of justice are very loth to hurry to death a human being.

The fact that a convicted murderess, relieved from the extreme penalty of the law on the ground of insanity, and committed to an asylum but a year ago, is now making what may be presumed to be a successful effort for restoration to absolute liberty, is but another argument in favor of the point we make, that popular sentiment in America is tending rather away than towards the idea of human vengeance. For, after all, it is but ven

geance. When a man is carried by passion or by liquor to the point that will induce him to kill a fellow-being, he has very little thought for the prospective punishment that awaits him. Of course, we all realize that capital punishment was not designed as an act of vengeance, but rather as a means of intimidation, of prevention against crime; but that it does not fulfil its intended purpose is, we imagine, becoming very evident.

Does it not seem brutal, to say the least of it, to put a rope around the neck of a man, and drag him up as we would a bull or a pig, until we have either choked the life out of him, or broken his neck? And does it not seem even more brutal when we realize that this action is taken by the order of men (and *a man* who for his assumed intelligence has been selected to sit in judgment on his fellow-men) who quietly and deliberately determine that a fellow creature shall be launched into eternity.

We do not for one minute wish to be understood that murderers should be allowed to go at large—by no means; but we do say most emphatically that no man, or body of men, can reasonably have the right to condemn a fellow-man to death. Murderers should be confined where they will have no power to work further mischief—this, we all concede; but at the same time, we can conceive of no right to *kill* a man because he has killed another.

It is the duty of physicians to enlighten the public on subjects like these; hence, we have felt called upon to write these words. In these days of civilization and advancement, let us consider well whether capital punishment is not a great blot upon our civilization, and let us look to it whether we are not harboring a relic of barbarism. Justice, law, and order, must be maintained; the man who interferes with the rights of his fellow-man must be punished; he whose liberty is dangerous to the welfare of his neighbor must be restrained of his liberty; but we again say that we doubt very much whether the proper way to accomplish this purpose is to deprive him of his life, and we imagine that popular sentiment joins in this doubt.

THE INCREASE OF THE OPIUM HABIT.

While visiting a patient in this city, we were led to inquire about a woman whom we had previously attended in the same house. The reply was that she had disappeared two days before, ostensibly going out for a walk. The suggestion proffered to our further questioning was, that "she was passing a day or two in an opium joint." No surprise was displayed at her disappearance, and evidently it was regarded as nothing unusual or noteworthy for one of her class to indulge in a prolonged spell of opium intoxication.

A few years ago such a thing was utterly unknown in the eastern United States; and when Dickens, in Edwin Drood, described such a den as he had seen it in one of the lowest slums of London, the English-speaking world scarcely understood him.

It is very different now. Here in Philadelphia, still more in New York, there has been a rapid introduction of opium-smoking during the last five years. There are no prohibitory laws against it, at least none that are effective; and the vice is all the more dangerous because it does not involve the victim in any public scandal, as does the act of drunkenness. The opium slave finds the "joint" fitted up with comfort, often in a quiet second-floor room, where the other indulgences of tobacco and liquor are also at his command. He can recline long hours in easy-chairs or on a sofa, and is not turned out at night to walk unsteadily home, as these places are for the use of their patrons at all times.

Companionship of both sexes, when he wants it, is at hand, for this seductive vice has its votaries in both. The woman who has lost her family ties and who has forfeited her own self-respect, finds in the dreams of opium that delusive happiness which she thought had forever been lost to her.

In his essay recently noticed in this journal, Dr. Meylert states that there are many indications that the opium habit is increasing in this country. He adduces several, and adds the suggestion, that doubtless many deaths of patients in hospitals and asylums, of prisoners, soldiers, etc., attrib-

uted to other causes, are really due to sudden deprivation of opium.

All experts are aware of the secrecy with which this indulgence is often guarded. Instances are not rare where a wife has for years been an opium habitué without the knowledge of her husband. We cannot form an estimate of its exact prevalence on account of this secrecy. But it is a formidable and increasing vice, commanding our most earnest solicitude; of this there can be no doubt.

COMPULSORY VACCINATION.

In a government of the people it is not always easy to draw the line between too great personal liberty and its just restriction.

Nowhere is this more difficult than in what pertains to the health of the community, and nowhere, we may add, are people more intolerant of restriction than in precisely this direction. That they should be asked to sacrifice, or even to jeopardize their interest to protect the health of others, is something they are very unwilling to admit. This is constantly seen in matters of quarantine and embargo. They ever encounter an active opposition even from the parties for whose benefit they are created, let alone from those who are only indirectly gainers by them.

The prejudice against compulsory vaccination is equally obstinate, although in this case it cannot be averred that such a measure interferes with anybody's profits, or with the sacred laws of trade. The opposition is indeed largely sentimental, and absolutely devoid of rational basis.

It arises in part from the dissemination of false information by a set of alarmists, who thereby seek a little notoriety which they cannot get through more creditable means, partly from a sensitiveness lest the liberty of the individual should be encroached upon in other ways if this entering wedge be allowed.

Nearly all the most intelligent members of the profession are distinctly in favor of such legislation. This is illustrated by the experience of the State Board of Health of Indiana. That body sent out a number of circulars to the principal physicians of the State, asking their views on this important subject.

All [the reporters but one were positively in favor of compulsory vaccination as provided in the questions given. One considered such a rule to be "undemocratic." Others provided that such vaccination should be with humanized virus.

Compulsory vaccination, as considered by the committee, meant vaccination of all persons at suitable times. Admonition should always precede the enforcement of the rule, and the approach of the complete application of such rule or law should be gradual; but in times of imminent danger, such as the approach of an epidemic, or actual appearance of a case of small-pox, all the members of a community should be compelled to undergo inspection, and if not protected, to be vaccinated. As a part of this gradation of enforcement, no one should be permitted to attend any school or institution of learning, either as pupil or teacher, without first having been vaccinated.

There can be no reasonable doubt of the excellent results accruing from such an enactment; and it is entirely consistent with the most liberal construction of our theory of government.

NOTES AND COMMENTS.

Nephrectomy.

The *London Medical Times* tells us that the literature of nephrectomy, a subject which has lately been somewhat prominently discussed, has recently been enriched by an account of a case to which its author rightly prefixes the term "puzzling." Abdominal section was performed on a woman, aged 52, for the removal of a large tumor due to calculous pyonephrosis of long standing. It is stated that the parts were much matted together, and that the pedicle of the tumor was transfixed and secured with a single ligature, being attached at the same time to the edge of the wound. The case did exceptionally well at first, but it was found, some hours after the operation, that no urine was being excreted, the bladder containing nothing but pus. On the second morning severe symptoms of uræmia set in, and a

fatal termination rapidly ensued, no urine whatever having been passed into the bladder since the operation. On post-mortem examination the remaining kidney was found to be healthy in every respect, with the exception of extreme anæmia and a rather excessive surrounding of fat. Microscopically, no changes could be noted in it. Unfortunately, no record is published of the visible results of the operation, except the fact that no peritonitis had taken place. The complete disorganization of the diseased kidney proved beyond doubt that all the urine must have been secreted by its healthy fellow for many months before the operation. Why, then, did the latter cease to excrete from the moment that the operation was concluded? It is to be regretted that more information is not afforded by Dr. E. Sonnenburgh, who reports the case in the *Berliner Klinische Wochenschrift*, No. 47, 1884, as to the exact structures included in the comprehensive ligature which was placed around the matted pedicle. Even on the supposition that some of the renal vessels or nerves had been so included, it would be difficult to account, however, for the production of simple anæmia, unattended by microscopical changes.

The Treatment of Gastrodynia.

The following instructive case of this obstinate and troublesome affection is reported in the *Medical Press*, December 17, 1884, by Dr. John W. Martin:

Miss R., æt. 30, came under my care October 3, 1884, suffering from pain in the stomach after meals, and the consequent dread of and loss of desire for food. When seen she looked quite worn and thin; complexion sallow; lips and gums anæmic; tongue whitish and lightly furred; bowels constipated. She felt a daily-increasing sense of weakness and inability to attend to her duties. Physical examination yielded negative results as regards the condition of the various organs. The case seemed one of dyspepsia consequent upon anæmia. The uterine functions were, with the exception of paleness of the menstrual discharge, normal.

I at first ordered bismuth, soda, and tr. nux vom. mixture with chloroform water; and calomel, colocynth, hyoscyamus pills to regulate the bowels. This giving no relief, I changed to pills of reduced iron and extract of nux vomica with meals, and as a laxative a mixture of sulph. mag. and mag. carb., with peppermint water. Again no relief being experienced, I placed her upon the following prescription:

℞.	Sodæ bicarb.,	ʒiss.
	Tr. nucis vom.,	♏xl.
	Liq. morph.,	ʒj.
	Sp. am. aromat.,	ʒiss.
	Syrupi zingib.,	℥j.
	Aquæ menth. pip. ad.,	ʒviij.

M. ʒj. to be taken four times a day.

The relief was immediate, and so far has proved permanent. Pain is now rarely felt, and only after indiscretions as to food. Relish for her meals has returned. She is now taking the reduced iron and extract of nux vomica pills with meals, and finds decided benefit from them. The bowels are regular, the tongue clean, and her complexion and general appearance much improved.

I am inclined to think the small dose of opiate was just the one thing wanting in my previous treatment, to help the lame dog over the stile.

Urea Not a Cause of Uræmia.

Before the New York Pathological Society (November 12, 1884), Dr. Peabody said that at the last meeting of the society he had expressed the opinion that too much stress had been laid upon urea as a cause of uræmia, his opinion being based more or less upon observations in the lower animals. Dr. Seguin had been of a similar belief, but spoke of experiments recently made, from which it would seem that uræmic symptoms might be produced in the lower animals by the injection of urea into the blood. Dr. Seguin had since informed Dr. Peabody where he could gain access to the records of the experiments to which he had referred, and Dr. Peabody took occasion to show to the society that it would require, according to the amount of urea necessary in these experiments to produce death by injection into the circulation of the dog, one pound and a half of urea to produce a fatal result in man. But it had been shown that in a man of one hundred and fifty pounds weight, dying of uræmia occurring in the course of kidney disease, the blood contained only nine one-thousandths of a pound of urea. There might be apparent fallacies in this manner of drawing conclusions, but he thought that it showed very conclusively that such experiments upon animals could give us little information as to the cause of uræmia in man. The injection into the blood of benzoate of sodium or sulphate of sodium, agents which were not in themselves poisonous, would likewise produce uræmic symptoms. The experiments cited went no further than to show that the injection of a certain amount of any foreign substance into the circulation would produce death; they

did not show that uræmia was due to the presence of urea in the circulation. He had seen several fatal cases in which there had been entire suppression of the urine, but none of the so-called uræmic symptoms.

Cocaine in Diseases of the Throat and Nose.

Dr. Morell Mackenzie thus writes to the *British Med. Jour.*, December 13, 1884:

"It may be interesting to know that I have found hydrochlorate of cocaine extremely useful in operations for the removal of nasal polypi. It is not enough to paint the growth itself, nor even the parts immediately surrounding its base; the solution should, as far as possible, be applied to the whole of the mucous lining of the nasal fossa. The remedy has also proved of service, in my hands, in those cases of laryngeal phthisis in which there is great odynophagia, owing to swelling of the epiglottis. Patients, who before could swallow only with extreme pain and difficulty, have been enabled to take food with perfect ease and comfort. The best time for swallowing appears to be about ten minutes after the application, whereas operations can be done after an interval of from three to five minutes. The difference is probably to be explained by the fact that in the former case the patient feels himself, at first, unable to make the attempt to swallow, from the total abolition, locally, of all sensibility to nervous impressions. In all cases, the anæsthesia persists for about two hours. Apart from the restoration of the power of taking nourishment, much relief is given by the mere absence of pain. When it is remembered how much suffering is caused to patients with inflamed and ulcerated throats by the continual necessity of swallowing or coughing up the copious secretion which is so troublesome in these cases, it is a comfort to have at hand a remedy which renders these acts painless without in any way affecting the general system.

"Both for the larynx and for the nose I have employed a 20 per cent. solution of the drug, made for me by Mr. Martindale. I think it likely that this, or a somewhat weaker preparation, would prove a valuable remedy in hay fever, or might even prevent the attacks."

Strangulated Hernia—Aspiration—Recovery.

The following case, which Dr. J. H. Leslie Allen reports in the *Brit. Med. Jour.*, November 29, 1884, possesses much practical value:

"On Christmas Day, 1882, I was called in by Dr. Lawton to see a farmer, aged about 70, subject to a large right inguinal hernia. It was usually reducible, but on this occasion had become obstructed, and could not be returned, though Dr. Lawton had diligently and carefully applied the taxis, and tried all the usual accessories—enemata, fomentations, etc.—in the hope of overcoming the obstruction. The hernia was of great size, filling and distending the scrotum, and felt hard and tense from imprisoned flatus. This careful trial of the taxis having failed, it became evident that, unless relief were soon afforded, the patient would sink, as the symptoms of strangulation had been for some time becoming more urgent; yet the man was old and feeble, in bad health, and not likely to survive an operation. I therefore suggested aspiration of the flatus, and a renewed trial of the taxis. Dr. Lawton accordingly passed a small needle of the aspirator well into the distended gut, which soon became perceptibly more flaccid, and, on further trial by manipulation, the gut slipped up at once. A draught containing twenty minims of tincture of opium was then given, a hot poultice applied over the groin, and absolute rest enjoined. Next day the patient expressed himself as feeling well. Half a grain of opium was given morning and evening, to keep the bowels quiet; and, after a few days, recovery was complete, though it was difficult to keep up the hernia an account of the great size of the ring."

Phenic Acid in Malarial Fever.

Dr. Wm. R. Pryor thus concludes a paper in the *Virginia Medical Monthly*, October, 1884:

Reviewing all the cases I have seen in which phenic acid was used, I think its range of usefulness is very limited. In the first place its mode of administration is extremely painful; and, although I have never seen a case in which abscesses had resulted from its use, yet after a few thousand minims have been given hypodermically. the abdomen becomes extremely sensitive. I always give the solution warm and through one puncture. The resulting lump I paint over with tr. iodini. Again, when employed in very large quantities it does seem to have some effect upon the malarial poison. But it must be used in such quantities as seriously to endanger the proper performance of the function of the kidneys. I have never heard of a case of well-established intermittent fever being cured by this remedy alone. The most I have ever seen it accomplish is a slight amelioration, and that temporary, of the symptoms. I am only sorry that Case No. II. would not let me sacrifice his comfort a little longer to

the cause of science. The only circumstance where I would ever again use this method of treatment would be one where the stomach and bowels refused to retain quinine, and where hypodermics of quinia caused abscesses; or, in other words, it shall always be with me a last resort. Certain it is that it can never replace quinia preparations in the treatment of cases of malaria poisoning.

Cocaine in Sleeplessness.

Cocaine (or cucaine, as our English cousins call it,) has been recommended for a variety of purposes, and now Mr. J. Swain reports the following cases in the *Brit. Med. Jour.*, December 20, 1884:

Case 1. A man, aged 33, suffering from aortic disease and albuminuria, had been troubled with insomnia for a fortnight. Three minims of a 4 per cent. solution of hydrochlorate of cocaine (equal to $\frac{1}{8}$ of a grain) were administered hypodermically. The patient remarked that "he slept better than he had done for a long time." The following night, one drachm of valoid of coca (a liquid extract, each drachm of which represents an equivalent quantity of the pure drug) was administered. The man did not sleep well. Two drachms of the valoid of coca were then given, and sleep was induced. The patient has continued to take this dose nightly for the past three weeks, the sleep being natural and undisturbed.

Case 2. Two drachms of the valoid were given with an equally beneficial result to a patient convalescent from an empyema, and suffering from sleeplessness.

Case 3. A woman, with tertiary syphilis, was kept awake by pain in a large rupial sore on the thigh. Two minims of the 4 per cent. solution of the hydrochlorate of cocaine, dropped on the ulcerating surface, relieved the pain, and the patient slept.

To show that coca and cocaine have no toxic action—at all events, in moderate doses—it may be worth mentioning that, in a case of rheumatism, the dose of hydrochlorate of cocaine was gradually increased to six minims ($\frac{1}{4}$ of a grain) hypodermically, and the valoid increased to five drachms, without any bad effect.

Permanganate of Potassium in Gonorrhœa, Leucorrhœa, and Suppurating Buboes.

Professor Roberts Bartholow thus writes in the *Medical News*, November 22, 1884:

In gonorrhœa, leucorrhœa, and suppurating buboes, a strong solution—five to ten grains to the ounce—is an efficient remedy. It has proved to be especially so in gonorrhœa. When the attack is recent, the solution should not be stronger than two grains to the ounce, but the more chronic, the stronger the injection may be made, of course within reasonable limits. In suppurating buboes, the contents of the sac should be drawn off with an aspirator if still intact, or thoroughly evacuated if ruptured, and the cavity filled with the stronger solution mentioned above.

Lacerda's experience with permanganate in snake poison renders it almost certain that in the corresponding poison of syphilis the local application of this remedy at the earliest moment to an infecting chancre may be productive of the best results. In all forms of unhealthy and sloughing syphilitic sores—in sloughing phagedæna, for example—it deserves more extended use than has heretofore been made. Finely pulverized, it can be dusted thoroughly over the diseased surface and introduced into all the sinuosities. By the same mode of application it can be used in lupus and epithelioma, and will, doubtless, be found more effective than the chlorate of potassium, which, applied in this way, has lately been much urged on the attention of the profession.

Kussmaul's Coma.

Before the Midland Medical Society (November 19, 1884), Dr. Saundby read a paper on Kussmaul's coma, based upon two recent cases. He described its symptoms, drawing attention to the peculiar character of the dyspnœa as constituting a distinguishing feature of pathognomonic significance. He especially insisted upon the fact that this form of coma was not restricted to diabetes, one of the cases related being an example of its occurrence in advanced renal disease. He referred to the various theories which had been advanced to explain it, and stated precisely the exact position of the acetonæmia question. He explained the methods used for testing for acetone, and showed Nobel's test with nitro-prusside of sodium and ammonia. In his opinion, the symptoms were due to the action of some poison nearly allied to acetone. He referred to Minkowski's suggestion that they might be the result of de-alkalization of the blood from the presence of some acid in great excess. After discussing the predisposing and exciting causes and the diagnosis, he pointed out that it was not invariably fatal. Treatment in the early stages should be eliminatory, by purgatives, if the bowels could be got to act, and later on the intravenous injection of a neutral saline solution should be tried. The re-

sult in one case was to restore animation for the time; and where recovery was possible, more permanent results might be expected.

Infantile Diarrhœa.

In the *Med. Press*, November 26, 1884, are published some notes of a paper on this subject by Mr. O. Lankester, which treated of simple diarrhœa unconnected with organic diseases of the intestines. He divided the subject into the four varieties of non-inflammatory diarrhœa, inflammatory diarrhœa, choleraic diarrhœa, and dysentery. Of these four he considered only the two first varieties. He mentioned cold, bad feeding, dentition, and worms, as the chief causes, and sketched out the diet of infants. He mentioned the complications of diarrhœa, as blood in the stools, prolapse of rectum, and spoke of the use of opium in connection with the latter. Mr. Lankester next alluded to the uncertainty of diagnosis in cases of diarrhœa caused by dentition. With regard to the inflammatory diarrhœa, the causes may be the same as those of simple; also bad smells. In considering the question of diet, he spoke of the necessity of avoiding the use of milk, and advised the substitution of broth, also white wine in cases where collapse is present. He alluded to the use of mustard baths and brandy, and an antiseptic treatment, washing out the stomach, and small doses of soda benzoates frequently. In cases of chronic forms of inflammatory diarrhœa, the utmost attention should be paid to diet, and pepsin and raw meat are very useful.

Witch Hazel as a Hæmostatic.

Dr. W. O. Bridges thus writes in the *Therapeutic Gazette*, October, 1884:

"The editorial reference in the August number of the *Gazette* on Witch Hazel in Menorrhagia, attracted my attention on account of the seemingly beneficial results which have followed the use of the drug in various forms of hemorrhage, in my recent practice. I was prompted to its use by Ringer, who recommended it in all varieties of passive hemorrhage, his favorable results having been obtained with it particularly in hæmaturia and bleeding piles. Within the past few years I have prescribed it for bleeding piles, menorrhagia, and continuous bloody oozing from the uterus four weeks after confinement. In each one of these cases there was no further trouble after twenty-four hours. The doses which I gave were somewhat smaller than those referred to in your article. I followed Ringer's plan of giving two drops of the fld. extract hourly. I was skeptical in regard to its use at first, but inasmuch as no other remedies were prescribed at the same time in the cases referred to, nor even rest enjoined, I was inclined to give witch hazel the credit. Other uses for which Ringer recommends its trial are pulmonary hemorrhages, hematemesis, and varicocele.

Boracic Acid Oil in the Treatment of Burns.

In the *Brit. Med. Jour.*, December 20, 1884, Dr. C. J. Bond says it is now a year since he began to use boracic acid oil as a dressing for burns at the Leicester Infirmary, at first simply in the form of a mechanical suspension of the powdered acid in olive oil. He has found that 18 grains of powdered boracic acid dissolved in a drachm of hot glycerine, and added to an ounce of olive oil, forms a kind of imperfect emulsion, the glycerine retaining the acid in solution when cold. This can be easily shaken up with the oil. This makes a non-irritating and doubly antiseptic dressing, and extensive burns treated thus, and covered with a layer of some antiseptic wool, require to be disturbed but seldom, and if not perfectly aseptic, are far "sweeter" than when dressed with, for instance, the carron oil.

As a lubricant for catheters, sounds, etc., this boracic oil with glycerine possesses advantages. It is superior to olive oil, because of its antiseptic property; and better than carbolic oil, because it is less irritating and much more stable; boracic acid being non-volatile. Glycerine itself, too, is a dressing of considerable value by virtue of its dehydrating power.

A Contribution to the Clinical Study of Rotheln or German Measles.

It appears to be a somewhat general opinion that Rötheln, or as it is not infrequently called, German measles, is a disease of such minor importance as to be unworthy of scientific research; but a disease, the victims of which succumb as early as the fourth day, must be of sufficient importance to demand our attention and the best efforts of our armamentarium.

Dr. W. A. Edwards, during the winter and spring of 1881–2, studied in the Philadelphia Hospital over one hundred cases of the disease, and the results of his observation he details in a valuable clinical paper in the October number of *The American Journal of the Medical Sciences*.

As regards the diagnosis, he says the eruption appearing on the third day, first in the face, its

rapid extension, its gradual shading off into the surrounding skin, its elevation, more particularly in the centre of the patch, which is also the brightest in color, together with the fact that desquamation first shows itself there, are all points, which, as far as the eruption is concerned, render the diagnosis plain; furthermore, the rash almost at once occupied whole the body, and never presented a crescentic outline.

Hydrochlorate of Apomorphine.

In *Squibb's Ephemeris* for November, 1884, we read that hydrochlorate of apomorphine is one of the new preparations of the present Pharmacopœia, but it is very little used and of doubtful general utility. The two principal objections to it are, first, that it is uncertain, harsh, and dangerous in its action, and probably has as many casualties charged against it, considering its limited use, as any remedy proposed within the past fifteen years. Secondly, it is unstable in composition, and especially liable to change, and becomes partially or wholly inert by keeping.

Its single point of value seems to be that it is a prompt, though not very certain emetic, whose action is said to be directly upon the nervous centres, and not reflex. Therefore, when given hypodermically, it will empty the stomach by emesis, provided the nervous centres are still sensitive to its action. This peculiarity of action is supposed to adapt it to the evacuation of all poisons from the stomach, except the narcotics in the later stages of their action.

Subcarbonate of Iron in Surgery.

In an article in a recent number of the *Journal de Médicine* of Brussels, Dr. Timmermans calls attention to the great advantages possessed by the subcarbonate of iron in the treatment of wounds and ulcers, and especially when these last are chronic, as it causes too much pain as long as any inflammation is present. He regards it as efficacious as iodoform, without its disagreeables and dangers. In recent wounds it arrests hemorrhage and hastens cicatrization, and recent ulcers due to excoriations or contusions are rapidly healed. After the ulcer has been washed and dried, its surface and edges are covered with a layer of the powder from one to three millimetres in thickness, over which is placed a pledget of charpie or lint, and a bandage. During the first days the dressing is renewed from two to three times a day, according to the amount of discharge. Care must be taken not to allow of accumulations of pus, it being necessary that the iron should be in direct contact with the ulcerated surface.

Nerve Suture and Excision of Bone.

The following novel operation was recently performed by Professor Von Bergmann in the Royal Clinic at Berlin:

A boy, aged 15, was brought there, who, in June of last year, had been severely wounded in his right upper arm by a circular saw. The wound had healed up in about ten weeks; but the boy had lost all power of motion, and all sense of touch, in his right arm and hand. It was supposed that the nerves of the upper extremities had been severed; and, in order to reconnect them, the scar was reopened, and the ends of the nerves uncovered. As it was impossible to join them as they lay, a piece of the humerus, two inches long, was sawn off. The two ends of the nerve were then joined, and it is hoped that the boy will recover the use of his arm and hand.

A Uterus Exhibiting the Results of Trachelorraphy.

To a recent meeting of the West London Medico-Chirurgical Society (Oct. 3), Dr. Imlach showed this specimen from a patient who died of cancer of the stomach four months after performance of the operation of trachelorraphy in the Hospital for Women. Before operation there was deep bilateral laceration, and the cavity of the uterus measured 3½ inches. At the time the speaker received the specimen, the cavity of the uterus had diminished to 2½ inches, thus showing, as he claimed, the beneficial results of the operation. He next showed a fibrous tumor, from the vaginal wall, and remarked that such tumors were very rare, they not being even mentioned by either Edis or Thomas in their works.

Hazeline in Menorrhagia.

In the *Practitioner*, August, 1884, p. 141, Mr. M. Chute describes a valuable remedy for menorrhagia, which is a very frequent ailment in women in Cape Colony. Two drachms of hazeline, given twice or thrice a day, will act so quickly that it is not necessary to anticipate the flow; but when menstruation, after it has lasted the ordinary time, is not closing naturally, hazeline, given as above, will effectually restrain it, and after hemorrhage has ceased there is no advantage in continuing the drug. Another good result produced by hazeline is, that it relieves the pain

of dysmenorrhœa in a very quick and marked manner.

A Case of Resection of the Pylorus for Carcinoma.

In the October issue of *The American Journal of the Medical Sciences*, Dr. Randolph Winslow, of Baltimore, reports with full details, an unsuccessful case of pylorectomy performed with antiseptic precautions upon a woman aged 42, suffering from carcinoma, who, in her own words, was "dying every day." She survived the operation two hours.

Correspondence.

An Interesting Case of Dislocation at the Knee.

Eds. Med. and Surg. Reporter:—

November 6, 1884, I was hastily called to see Walter Duncan, æt. 6, who, while in his "high chair," turned it over, the entire force of the fall being on his right foot.

I found him suffering greatly; the leg flexed almost to a right angle upon the thigh, and held so by clonic contractions of the hamstring muscle. Using some force, the limb was straightened, and I readily diagnosed dislocation of the tibia forwards. The patella lay in a depression just above a protuberance—the head of the tibia—and could be readily raised in the fingers. The condyles pressed hard into the popliteal space. The limb was three-fourths of an inch shorter than its fellow, and at once returned to its position of right angle to the thigh upon its release.

It was readily reduced over my knee, coming into place with a slight snap. It was placed upon a posterior splint with a foot-piece, by means of which slight extension was made, and bathed with a solution of lead-water and laudanum to allay inflammation, which, for three days, ran high, necessitating the use of morphine to control the pain. At the end of twelve days the posterior splint was removed, and a "Bavarian" plaster splint applied. Passive motion was begun the same day. The patient was able to walk with the aid of crutches at the end of the third week, and at the end of the fourth the splint was thrown aside and the knee encased in a laced knee-cap, which he still wears. He at this writing has as good use of this limb as his left, all stiffness having disappeared.

I thought this case worthy of publication, not only because of the rarity of luxations at the knee-joint, but also because it presents two interesting features.

The first of these is the age of the patient. The youngest case on record of which I have knowledge; the next being that of a boy æt. 10, the patient of Dr. White, of Buffalo, N. Y.

The second feature I desire to notice is the position of the limb, that of flexion almost to a right angle, while we would expect dorsal flexion of 30° or 40°. I can account for this only in this way: that there was extensive laceration of the ligaments (a supposition which the subsequent inflammation confirms), and that the hamstring muscles did not slip over the condyles as they usually do.

Spence Redman, M. D.
Platte City, Mo.

News and Miscellany.

Causes of Death in New-Born Children.

Dr. Nobiling, of Munich, whose labors in forensic medical research have earned him the reputation of a high authority in Bavaria, has recently published in the *Ærztliches Intelligenzblatt* a series of contributions on the pathological appearances observed in the bodies of children that have died from asphyxia shortly after birth. He has examined a large series of bodies, and has arrived at the conclusion that the asphyxia often attributed to overlying, and even to obscure pulmonary disease, is too often due to foul play. He is particularly suspicious of extravasations of blood, and sums up his conclusions on that subject. Extensive subcutaneous extravasations could always be traced by Dr. Nobiling to external violence, including such as might be received in protracted and instrumental labor, and attempts to restore animation. Effusions of blood in the muscles of the neck and along the course of the great vessels are always caused by forcible strangulation. Hemorrhages under the capsule of the liver or in its substance are invariably the result of external pressure, and so are lacerations of the peritoneum, liver, spleen, and kidneys. These injuries are by no means rare results of violent attempts to promote respiration, and Dr. Nobiling has traced them also to rough and clumsy handling of a new-born infant by male relatives or incompetent nurses. Hemorrhages in the tissues of the umbilical cord are very rarely caused by the mechanical forces of labor, or even by artificial replacement of the prolapsed cord; they generally result from firm manual pressure on the cord, or from intentional laceration. Circumscribed collections of blood under the scalp or integuments may be either due to mechanical labor, or to many other kinds of external violence; the same applies to hemorrhages in the substance of the lips, tongue, palate, and pharynx, which are always traumatic. Bleeding from the external auditory meatus and extravasations behind the ear are also the results of violence, not disease. Dr. Nobiling has often found a portion of the fluid or solid material which caused the infant's death in the nasal fossæ, mouth, larynx, trachea, bronchi, pulmonary vesicles, œsophagus, stomach, tympanum, or Eustachian tube, sometimes in only one of these anatomical structures and regions. When blood is found lying free in the same parts, it may have proceeded from the infant's nose, or have entered its mouth during parturition, being of maternal origin. The principal lesson to be learnt from the researches of Dr. Nobiling is that all internal and intestinal extravasations of blood in the body of an infant are to be regarded with suspicion, and to be considered as traumatic, being due to violence causing visceral injury, or complete and sudden asphyxia.

THERAPEUTICAL NOTES.

Crystal Pepsin.

The surgical value of pepsin as a dissolvent is well shown in a note in the *Northwestern Lancet*. The editor of that journal states that he was once called upon to relieve the distress occasioned by a bladder distended with clotted blood. He injected a scruple of Jensen's crystal pepsin in an ounce of warm water, and had the satisfaction of seeing the patient pass a full stream of urine and disintegrated blood, in less than twenty minutes.

Peptonized Cod-Liver Oil.

This valuable form of cod-liver oil is prepared by Messrs. Reed & Carnrick, of New York city. It is a combination of pure cod-liver oil and condensed milk digested, the oil being artifically prepared for assimilation with nature's emulsifier—pancreatine, instead of gums, alkalies, Irish moss, and water. It will keep indefinitely, having been tested for over a year at a decomposable temperature. It is prepared with milk and also with hypophosphite of lime and soda.

We observe that among the food products exhibited at the International Health Exhibition, London, 1884, from the United States, were *beef peptonoids* and *maltine*, products of the same firm. Both of these preparations carried off the gold medal and highest award against numerous competitors in their respective classes. All food preparations were critically analyzed at this Exhibition by a jury composed of the best chemists in the country.

Medicinal Wines.

For medicinal purposes the pure Hungarian wines imported by Mr. L. Reich, of New York, have stood the test of years, and deserve the highest encomium. He makes his selections with intelligent and conscientious care.

Supervision of Noxious Trades.

Before the Society of Medical Officers of Health (England), November 21, 1884, Mr. Alfred Spencer, of the Metropolitan Board of Works, read a paper on this subject. He referred, in the first instance, to the effect of the Metropolitan Building Act of 1844, section 55 of which prohibited the erection of any dwelling within fifty feet of a building used for the business of a blood-boiler, bone-boiler, fellmonger, soap-boiler, tallow-melter, tripe-boiler, slaughterer of cattle, sheep, or horses, and any other like business, offensive or noxious. It was also forbidden to carry on any such business within forty feet of any public way, and fifty feet of a dwelling; and any existing business of this character, within these distances, was to be abandoned at the end of thirty years. By themselves, these causes would have led to the abolition of such places within thirty years, but a later section gave the justices power to mitigate the penalty, provided the best means were adopted for preventing nuisance. In 1874 an Act was passed which repealed the last sections, and thus certain businesses came to be prohibited; while others could only be established by consent of the local authority. The Metropolitan Board of Works, under this Act, made regulations for slaughter-houses, which had been very beneficial in their operations, and as many as 620 out of 1,429 had been abolished. Offensive businesses were mostly situated in Bermondsey, in Belle Isle, Islington, and in Southwark. A second set of by-laws under this Act dealt with the business of a blood-boiler, a bone-boiler, a manure-manufacturer, soap-boiler, and tallow-melter. The means for preventing nuisance in these businesses was stated in detail, and Mr. Spencer then commented on the qualifications necessary in the inspector for influencing the masters and men engaged in them. A short account was then given of trades dealt with by the Alkali Works Regulation Act of 1881, which includes within its operations works for sulphuric acid, for gas-liquor, for nitric acid, and sulphate of ammonia. The supervision of these businesses was in the hands of inspectors appointed by the Local Government Board. Other businesses were then briefly considered, such as brick and ballast burning, cement-making, etc.; and, in conclusion, Mr. Spencer alleged that the London of today was far more free from nuisance resulting from trades, in consequence of the restrictions under which they were placed.

Specimens of Irish Sanitation.

From a foreign exchange we learn that the following are a few from many excerpts which illustrate the way in which the Irish Local Government Board administers the sanitary law under its control. We may remark that the state of affairs here recorded is to be found in one of the premier towns of Ireland, and much worse is to be found elsewhere throughout the country. At the last meeting of the Carlow Town Commissioners, Dr. O'Meara, medical officer of health, reported the existence of a number of nuisances, including an accumulation of manure and filthy material in a lane. He found nuisance dangerous to health, caused by the occupier keeping a donkey in the back room of his dwelling-house, and pig manure and other nuisance in his yard. A similar report in the case of John Rafter, who kept five pigs in his dwelling, was made. The following report was also read: "I inspected the ten houses. These houses consist of one room each, which serves as bed room and living room. At the rear are two privies, which are a mass of filth and abomination, and are supposed to serve as privy accommodation for the ten houses. In the yard there is a pool of fœtid, stagnant water, in addition to other filth. I am of opinion that it is impossible for healthy conditions to exist in a single room used for all purposes of eating, drinking, sleeping, and cooking." The following was read from Dr. Bolton: "I beg leave to state that as a rule dwellings are most unsatisfactory, particularly in the Newtown district, where, I may say, they are without exception unfit for human habitation, and in many instances life is shortened from the effects of the poisonous fumes arising from the coal of the locality being consumed in cabins without chimneys, or with very imperfect ones. I have condemned cabins in the Newtown district on former occasions, and they were closed, but after a short time the occupiers again got possession, and some of them are still existing in the dwellings."

Germany on Vaccination.

From the *Lancet* we learn that the German Commission appointed to inquire into the subject of vaccination has, with the exception of the three members opposed to vaccination, unanimously declared for vaccination with humanized lymph rather than with that from the calf. At the present moment we do not know upon what grounds this preference depends, but we assume that the fact is recognized that *direct* vaccination —*i. e.*, vaccination with lymph which is not stored—"takes" far better, and therefore gives much more protection against small-pox than vaccination with stored lymph. Vaccination with calf lymph throughout the country must necessarily be performed with stored lymph; but direct arm-to-arm vaccination with humanized lymph is a possibility everywhere. Calf-lymph has its use in enabling practitioners to renew their stock, and also in giving opportunity for the direct vaccination of numbers of persons in large centres of population. If in future it can be found that calves can be inoculated with small-pox virus and the virus modified by such transmission through the animal, it is probable that the use of calf-lymph will serve this purpose more than heretofore.

Indianapolis Academy of Medicine.

The Marion County (Indianapolis) Academy of Medicine, at their regular meeting, Tuesday evening, January 6, 1885, elected the following officers for the year 1885:

President.—Thomas N. Bryan, M. D.
Vice-President.—Alembert W. Brayton, M. D.
Secretary.—Ferree W. Frank, M. D.
Assistant Secretary.—Joseph O. Stillson, M. D.
Treasurer.—T. M. Rome, M. D.

The following gentlemen were elected as censors:

Dr. F. S. Newcomer, Dr. L. L. Todd, Dr. Geo. Cook, Dr. E. Hadley, Dr. R. E. Hampton, and G. V. Woolen.

The President appointed Drs. T. B. Harry, Brayton, East, Stillson, and Hodges as the Pathological Committee for 1885.

The Society listened to a paper by D. C. Bryan on "Stricture of the Urethra."

Items.

—The loneliest doctor in the world is the ophthalmologist who hasn't written an article on cocaine.

—Dr. Kolbe, of Leipzic, whose name is associated with the chemistry of salicylic acid, has recently died.

—Surgeon P. H. Bailhache, of the Marine Hospital Service, has been assigned to duty in Philadelphia.

—"Louis Pasteur: His Life and Labors," containing the life-work of this distinguished savant, has been translated into English.

—A drachm of balsam copaiba to an ounce of white vaseline makes an ointment popular with New York ophthalmologists in treating chronic conjunctivitis.

—The anæsthetist's bag should always contain a pair of tongue-forceps, a Fergusson's gag, a scalpel, forceps, and tracheotomy-tube, and a few capsules of nitrite of amyl.

—A child has recently died at Rye, England, from shock to the nervous system, caused by fright at seeing a boy wearing a mask. She lost her reason the first day after the occurrence.

—The publication of the *British Journal of Homœopathy* has been discontinued, and the editors, Drs. Dudgeon, John Drysdale, and Hughes, are to have a testimonial presented "for their eminent services to homœopathy."

—The announcement that Dr. R. von Leudenfeld has discovered histological elements having nervous functions in the sponges of the Australian shores, possesses considerable interest for biologists.

—Deep snoring, and an insensitive conjunctiva, are good signs of insensibility, but the most trustworthy one of all is subsultus tendinum of the fingers.

—The Board of Trustees of Columbian University, Washington, D. C., on the unanimous recommendation of the medical faculty, have decided to admit women to the study of medicine in that institution, with all the privileges heretofore accorded only to males.

—The Ohio State Sanitary Association will hold its second annual meeting at Columbus on the 5th and 6th of February. Full information as to the programme, railway rates, etc., may be had by addressing the Secretary, Dr. R. Harvey Reed, Mansfield, Ohio.

—During 1883, the six faculties of medicine in France conferred 662 diplomas of doctor of medicine, viz., Lille 20, Nancy 21, Lyons 43, Bordeaux 44, Montpellier 69, and Paris 465. During the same year 692 diplomas of doctor of medicine were conferred in Germany.

—According to Dr. Woodhouse Braine, in the *Brit. Med. Jour.*, November 29, 1884, to get the full effect of nitrous oxide, it must be given pure, all air being rapidly excluded; and if the patient wear a beard, it had better be wetted, or, what is more effective, have a little soap rubbed on it.

—A museum of hygiene, similar to the Parkes' Museum in London, will shortly be opened at Turin, and extensive purchases in the health department of the Exhibition have been made by Dr. Pacchiotti, who is one of the chief promoters of this useful institution.

—The *Lancet* learns that Dr. Klein and Dr. Gibbes, of the English Cholera Commission, have made a preliminary report in which they express themselves as entirely at variance with Koch. They deny the invariable presence of the comma bacillus in cases of cholera, and have been unable to inoculate the lower animals.

—Making a patient keep his eyes closed while recovering from the ether is a great aid in preventing sickness; for, owing to the patient feeling giddy, any object at which he looks appears to sway from side to side; and this, by itself, is sometimes enough to produce a feeling akin to

Treatment of cholera

In view of the [illegible] visit of the cholera to [illegible]ized. [illegible]ear any contri-

—If we wish to avoid sickness after anæsthetics, it is of the utmost importance that the patient should not be shaken when being lifted from the operating table to the bed; and if the operation have been performed on the bed, then the bedstead should be allowed to remain without being moved in the least for four hours, as the slightest movement is sometimes enough to start the vomiting.

—At a meeting of the Paris Hospital Medical Society, called expressly to consider the question of the projected admission of women as *internes* of the Paris hospitals, the meeting was addressed by Professor Verneuil in favor of the ladies, and after a brilliant reply by Professor Trélat, the vote was almost unanimously pronounced against the project, there being only four in its favor.

—Before the New York Obstetrical Society, Dr. Henry F. Walker mentioned a case that had come under his observation in which a lady became pregnant for the first time after seventeen years of wedded life. One year after her marriage the os externum was incised, but there had been no subsequent treatment directed to the removal of sterility.

—According to an analysis of the census taken in 1881, there were in all India at that time, among male British-born subjects, 321 "surgeons and physicians," 30 "apothecaries, hospital and medical assistants, and students;" 2 "unqualified practitioners," and 30 "chemists and druggists." Among the native population, in the inclusive class of "physicians, surgeons, and druggists," there were 123,579 males and 75,239 females.

—Local health officers in the State of New York are [illegible]ter to be appointed only after a com-[illegible]amination, in accordance with the new [illegible]ice rules. The examination papers are to be prepared by an examining board of five physicians, to be designated by the Civil Service Commission, and the examinations are to be held in the presence of a county judge, who will transmit the papers to the Commission.

—The *Medical Press*, December 17, 1884, publishes the following as an excellent pill in chlorosis:

℞.	Ferri sulph.,	
	Sodæ bicarb. ana,	ʒj.
	Pulv. tragacanth,	gr. vj.
	Syrupi,	q. s.

Divide into forty-eight pills, and let one be taken thrice daily. Later, two may be taken instead of one.

—Betz ("Memorabilien") states that the temperature of the bladder, and hence that of the urine contained in it, is affected by that of the surrounding tissues. Therefore, in inflammatory conditions of the pelvic cellular tissue and peritoneum, the patient often complains that her urine feels "hot." If cystitis can be excluded, it is quite probable that this symptom points to some inflammation in the neighborhood of the bladder.

—To a recent meeting of the Pathological Society of London, Mr. Treves showed a man who presented an extraordinary appearance, owing to a series of deformities, some congenital exostoses of skull; extensive papillomatous growths and large pendulous masses in connection with the skin; great enlargement of the right upper limb, involving all the bones. From the massive distortion of the head, and the extensive areas covered with papillomatous growth, the patient had been called "the elephant-man."

—In the *Æsclepiad*, July, 1884, Dr. Richardson gives a formula for the administration of amyl nitrite by the mouth:

℞.	Amyl nitrite, pure,	ℳxxxv.
	Ethylic alcohol (sp. gr. 830),	ʒv.
	Pure glycerine,	ʒiss.

To make a mixture of twelve doses. One fluid drachm to be taken in a wineglassful of warm water. In asthma this method is specially recommended.

—The Paris Medical Faculty has lost one of its most brilliant professeurs-agrégés in the person of M. Henninger, who died recently at the age of thirty-four, from tuberculous meningitis. His professorial thesis, on the action of soluble ferments on albuminoids, attracted great attention in the medical and scientific world. By competitive examinations he gained the position of Agrégé Professor of Chemistry in the Medical Faculty, and frequently took the place of the late Professor Wurtz in the professional chair.

—Dr. Lombe Atthill (*Brit. Med. Jour.*, November 29, 1884), says that iodoform, in the shape of slender crayons made up with gum, which can be passed through the cervical canal into the cavity of the uterus, has been recommended in the treatment of some forms of painful menstruation. He has tried it in these cases without much benefit. It may, however be used with advantage in cases in which a fetid discharge issues from the uterus, as is sometimes the case, in some forms of chronic endometritis occurring in elderly women.

—According to Dr. Thomas More Madden (*Brit. Med. Jour.*, November 29, 1884), for any intra-uterine treatment, it is essential, first, that the orifice and cavity of the uterus, if not already sufficiently patulous, should be mechanically expanded for this purpose; secondly, that, whatever application is employed should be brought into actual contact with the true intra-uterine surface. These propositions may appear too self-evident to need notice here. Nevertheless, any failures in intra-uterine medication arise, in nine cases out of ten, from their neglect.

QUERIES AND REPLIES.

EDS. MED. & SURG. REPORTER:—

In case of rupture or laceration of the hymen found post mortem ten days after death, the segments being capable of complete reconstruction, so as to restore the hymen to its normal form, there being very slight decomposition, how long before death must the hymen have been ruptured?

B.

[We doubt if any one could accurately answer this, unless he had himself carefully inspected the parts.—EDS. REPORTER.]

COMMUNICATIONS.

AN AUXILIARY METHOD FOR THE REDUCTION OF DISLOCATIONS.

BY H. ASTHALTER, M. D.,

Of Pittsburgh, Pa.

Many theories have been advanced to explain those causes and hindrances which sometimes make the best efforts to reduce a dislocation futile. The obstacle to the reduction has been looked for, especially by the older surgeons, in the contraction of the muscles, which, through the dislocation of a joint, are thrown out of equalization of action. And it cannot be denied that the contraction of the muscles plays an important part, and furnishes an obstacle, especially the moment an attempt at reduction is made. These contracted muscles will make the bone less easily movable, and draw it more or less tightly on the underlying one. The defenders of this theory thought if they could paralyze the muscles they would be able to reduce any and every luxation.

But the falsity of this theory has long ago been made apparent by the fact that in some cases the dislocations of joints (artificially produced) on the cadaver could not, in spite of expert efforts, be reduced.

Then, further, in some cases all the tendons of the muscles that could make any resistance were severed with the knife, yet the reduction was impossible. Again, the fact that the dislocation of the ends of the fractured bone produced by the contraction of the muscles is easily overcome by mild extension. And we may add that, in later years, the administration of anæsthetics has proven beyond all doubt that this theory, seeking the sole cause of hindrance in the contraction of the muscles, cannot hold good.

The principal hindrance, Malgaigne (as cited by H. B. Schindler) thought, was to be found in the friction of the dislocated head and the underlying bone. Although we always have friction to contend with when manipulating a dislocation, yet we believe it to play but an unimportant part; of course, in this particular, the irregularities of the region bordering immediately on the articulating surface of nearly all bones must not be overlooked.

Others looked for the difficulty in the capsule itself, and here there are different conditions possible; first, it may be a fibrous bundle torn from the one or other side of the capsule, and crowded between the articulating surfaces. Roser has shown this condition to occur, and really to be the hindrance in some of those cases of dorsal luxations of the thumb, where every effort at reduction has failed.

Secondly, it may be owing to the capsular tissue being flexible. The capsule itself is first violently distended in one direction before the rupture takes place, when the wound or rent will actually be smaller than the body that just passed through it.

This difficulty will be increased as soon as the edges of the rent become swollen and render the capsule less pliable, as it also tends to make the opening, which is necessary for the return of the luxated head, more difficult to pass. As far as my own opinion is concerned, I have always thought that the smallness of the rent in the

capsule was sufficient to explain the difficulty in the majority of cases.

Again, undoubtedly, there are cases in which a tendon or a bundle of muscular fibres, or a sesamoid bone, or all, as easily imagined, get between the articulating surfaces and make reduction difficult or impossible.

After E. H. Weber's discovery, that atmospheric pressure was a factor in retaining the head of a bone in its socket (for instance, the hip-joint). Voelkers, of Germany, maintained that this was the only obstacle we had to contend with in the treatment of dislocations.

Further, when swelling and inflammation of the region of the joint are present, they in various ways constitute a formidable drawback to reduction.

In the pre-anæsthetic period many ways were resorted to to produce the relaxation so necessary for the reduction of a dislocated bone. The method most frequently resorted to was venesection, continued until fainting set in. Others gave opium until its narcotic effects became apparent. Again, some made use of the alcoholics, to the same extent. Powerful emetics, as well as hot and cold bandages, were resorted to quite often.

But since the introduction of anæsthetics, these methods have all been brought into disrepute. And even with this assistance we have seen, in some cases, extreme force resorted to where mild and intelligent manipulation would easily and surely have succeeded. We must not forget, the moment blind force is resorted to, that we are really not doing any more than the henchman (scharfrichter) and shepherd of olden times, in whose hands this branch of surgery, before it was reduced to a science, used to be (at least in Germany), with the exception of some few cases. We can never say positively with what degree of celerity the bone may slip back into its place. The anæsthetic saves the patient all pain, and allows us to make every manipulation which we by experience (and the nature of the dislocation) know to be appropriate; still we think it wrong to apply the same in every case. Anæsthetics are quite safe, but not absolutely so. My experience with chloroform has put me on "my guard" in the use of this narcotic, and I will relate to you a few cases which may be of interest. I have seen three deaths occur while the operation was being performed, death in each case being superinduced by the anæsthetic. The operation each time was performed by our professor of surgery, and the anæsthetic administered by expert assistants. The first patient died of asphyxia, the result of spasmus glottidis. He was a robust, hearty man, 43 years of age; he suffered from a panuritium sub-periosteum of the left index finger. When this was to be lanced, he refused to undergo such a slight operation, unless he was put under the influence of a narcotic. The latter had been scarcely applied three minutes, when he showed symptoms of asphyxia, whereupon tracheotomy was immediately made, but the man was dead.

The second patient was a lady about 50 years of age, whose general health was moderately good, and who was operated upon for cancer of the left mamma. After the operation was completed and the Lister bandage was being adjusted, the patient suddenly became pale and expired.

The third patient was a male, 17 years old, somewhat pale and emaciated, who was being operated upon for pes varus after the method of Davies Colleyes. The operation was about one-half completed, when the action of the heart became suddenly weak. A hypodermic injection of moschus was immediately made, but the patient rapidly sank, and in a few minutes the breathing ceased entirely.*

The first patient received about 8.0 (℥ij.) of the narcotic (chloroform); the second about 120.0 (℥iv.); and the third about 60.0 (℥ij.). I need scarcely remark that every effort toward resuscitation was made by the operator and his assistants (of whom I was one).

The fact that local anæsthesia can be brought about by pressure is generally known. Hyrtl relating the experience of Hunter says, a man whose crural and sciatic nerves were made numb by a pelott well bound on each nerve, was amputated (exact place of amputation not stated). The man was of a very sensitive nature, and for this reason the experiment was made. After the vessels had been ligatured, the pelotts were removed, when Hunter discovered a small vessel which had been overlooked, bleeding, and while adjusting a ligature on this one, the patient manifested more pain than during the entire operation.

Since the invention by Paré of the tourniquet, the knowledge that when sufficient pressure was brought to bear on a nerve anæsthesia would be the result was general.

Tamburini, in citing Brissaud and Richet, says they found (in the hypnotic state of the patient) that the latent contractility of the muscles of an extremity, made anæmic with the Esmarch band-

*The diagnosis of the last two cases was paralysis of the heart.

age, returned only after removing the bandage, and with the return of the circulation of the blood.

It is well known how completely a swelling dependent on obstruction to the return of the venous blood will disappear upon the application of pressure.

Anæmia, generally speaking, conveys the idea of insufficiency of blood, a lack in quantity, or better, a defect in quality. But the anæmia artificially produced in an extremity with the elastic bandage is entirely different. Here we have not only an entire absence of blood, but of all lymph and residual fluid that may be in the tissues (bone tissue is here excluded).

When the blood and serum retreat before the applied bandage, the result must be that the walls of the capillary spaces will enclose upon each other. This enclosure of the walls of the capillaries, as well as the capillary spaces in the tissue, will cause a shrinkage of all the tissue, brought under the influence of the pressure. That this shrinkage actually takes place (as it can theoretically be expected) I have proven to the satisfaction of myself, by actual measurements made of the circumference of an extremity, before and after the application of the bandage. Why we do not see any wrinkles of the skin I can only explain from the fact that the skin is elastic and can lessen its dimensions or shrink without wrinkling, and again, on the ground that the adipose tissue, where it is present in heavy layers, will be sufficient support to hold the skin smoothly. That shrinkage takes place is beyond all doubt; the question arises with us, of what value is this shrinkage in luxations? It is plain that if pressure will lessen the size of all the tissues brought under its influence, then not only swelling that may be present will partially or entirely disappear after applying pressure, but also the natural size of the tissue will be reduced. It follows then that the general swelling of the tissue, which will be reduced in size, will shrink and make the way for the returning head of the dislocated bone more spacious and easy to traverse. Nearly all local swelling of an acute nature is the result of pressure, whether the capillary vessels are enlarged by temporary paralysis of the vaso-motor nerves, or whether the capillary spaces are filled up and distended by migrating cells. The pressure may also be of the purely mechanical kind, as for instance in paraphymosis.

Any method which consists in the application of an Esmarch or an India-rubber bandage in the same way as Esmarch has recommended for amputation and sequestrotomia, has for its object first, to reduce swelling (cause shrinkage); second, to create partial or complete anæsthesia; third, to throw the muscles out of action.

To gain this object the bandage must be tightly adjusted, and its central or upper end must be brought to bear on the origin of those muscles that may pass to or beyond the dislocated joint. The method can be applied only to those joints peripheric from the shoulder and hip-joint. No physician need have any fear whatever to apply the elastic or rubber bandage as tightly as it lies in his power.

Those cases reported from Langenbeck's clinic and elsewhere, where damage was done especially to the nerves, were due to the use of the flat tube as originally applied by the inventor. This tubing has been discarded in Germany, and the rubber bandage adopted in its stead.

The indications for the use of the elastic bandage are:

First. In those cases where a diagnosis is not possible owing to the swelling. The swelling resulting from dislocation is usually very painful, and an anæsthetic should always be used.

Second. Where, after repeated attempts with or without an anæsthetic, the reduction was not successful. In such cases we may assume that the capsule or the edges of the rent may be swollen; a bundle of fibrous or other tissue may have lodged itself between the articulating surfaces; therefore, the even pressure of the elastic bandage tends to make the parts lax and cause shrinkage. It seems to me the results with this method will be particularly gratifying when applied to the luxations of the smaller joints. (It is estimated by the different authors that from one-third to one-half of the dorsal luxations of the thumb are irreducible.)

Should a case of this nature be brought before us, and after having used mild manipulation and force without success, then the question arises, What shall we do? We can perform an operation, having for its object the severing of the tendons and other obstructing tissue, or the excision of the joint. This operation requires skill, and, like all operations, is not without danger, and the result is by no means perfect in all cases. Otherwise, the patient will be left to his fate; that is, to leave the thumb in its dislocated position. Our inability to reduce the dislocation will deprive the patient of the use of one-half of his hand.

We see this method is limited to certain joints and certain conditions. That the method is pain-

ful we will admit; but the time to resort to it is when the manipulations that are practiced by the expert surgeons have failed to reduce the luxation.

Aside from the object of this method, we think it ought to be applied in those cases indicated above, for the following reasons:

First. There is only ordinary skill necessary for its application.

Second. It can be applied in from five to fifteen minutes.

Third. It leaves *no injury behind.*

Fourth. We will by this method, in nearly all cases, save the patient the pain and risk connected with an operation that is, at its best, doubtful in its results.

To satisfy myself as to the value and practicability of the application of pressure in cases of luxations, I made a series of experiments on the elbow-joint of the rabbit. For several reasons this joint is the only one that can be used for this experiment. But even here we have such a strong capsular ligament and a long, upwardly-curved olecranon, and very high processus corono ideus, to contend with, that sometimes a fracture was much easier to produce than a luxation. I accordingly severed subcutaneously the anterior part of the capsular ligament, and in this way was able to produce a posterior luxation of the ulna. Although a luxation brought on in this way can in nowise be compared with those brought about by accident, yet my results (with the aid of the bandage) were so favorable that I feel justified in publishing and recommending this method.

As already stated, we admit that this method is painful; yet if the indications above set forth are strictly adhered to, the question of pain cannot be taken into consideration.

In conclusion I must say that should success not attend the first application of the bandage, then another similar application must be made. The central bandage must remain in its position while the peripheral one is being readjusted. Now after the readjustment of the peripheric bandage, the central one must be removed and re-applied as before.

3716 *Butler street.*

INEBRIETY A DISEASE.

BY G. C. ROY, M. D.,

Professor of Materia Medica, etc., Southern Medical College, Atlanta, Ga.

The editorial comments with the caption "A New View of Inebriety," in the REPORTER of November 15, upon the article of Dr. T. D. Crothers, published in a late number of the *Alienist and Neurologist*, make the opinion of Dr. C. so in accord with the views I have for a long time held upon this subject, that I cannot forego the opportunity of reporting some cases which have come under my observation, and which, in my judgment, corroborate these views.

Quite a large experience, and very careful observations with this class of unfortunate individuals, compel me to the belief that with many *inebriety is a disease*, apparently inherited and likewise contagious; and where this inherited predisposition exists, resistance to the contagion is almost beyond the power of the victim.

We see this in relation to other diseases; and why may not drunkenness be controlled by the operations of the same law?

Of many cases which present themselves to my mind, I will give only two:

1. Over 35 years ago, when a boy, I accompanied my father on a professional visit to a most accomplished gentleman and cultivated physician, then ill with what proved to be his last sickness. His constitution had been wrecked by periodical sprees extending through a number of years, but his mind was clear and brilliant, and his conversational gifts, as always, unusually fine.

On this occasion, in giving my father a history of his life, he remarked, that as long as he remanied at his home, in an adjacent county, that he never felt the desire for intoxicating drinks, and he often remained there, successfully engaged in his profession, twelve or eighteen months, without even the *desire* to indulge; but whenever occasion called him to the "old homestead," in the adjoining county, and he had crossed the line dividing the two counties, there came upon him, like a deadly nightmare, an indescribable desire for strong drink, which he could not prevent or avert any sooner or easier than he could withstand a glass of water when suffering from the most intensely burning thirst imaginable.

Now, this morbid desire would possess him as soon as he crossed the county line—at times when he had not been drinking for months, when he had all his reasoning faculties about him, and when he was struggling with himself to prevent just such a calamity as had so often and so sadly befallen him under just such circumstances. Now what was this but a contagious disease, the contraction of which, his system being ripe for it, he could not ward off any more than he could prevent an unseen attack of small-pox, or any

contagious disease to which he may have been exposed?

It is a fact, that as soon as he would recross this fatal county line on his return home, this strange disease would leave him, and he would have no thirst for strong drink, even after a terrible debauch.

This gentleman had several brothers, all of whom, so far as I know, suffered from this terrible disease, and died naturally or by violence at a premature age.

All of these parties were citizens of my native State—Virginia. Now, whether this influence is mental or physical I am not prepared to say, but am inclined to believe it is both.

2. I have now in charge one of the most highly-cultured ladies I ever met, a widow, young, handsome, and well-to-do, who is another sad victim of this dreadful malady. About four years ago I was called to see her for insomnia and extreme nervousness. We were then entire strangers to each other, and I knew nothing of her past history. I gave her a recipe containing ammonii bromid. with tr. hyoscyami; but having been recalled in the next twenty-four hours, I was informed by her mother that the medicine had made no more impression than so much water, and then for the first time I was very delicately and reluctantly told by her mother that she feared her daughter's unhappy condition was produced by excessive indulgence in alcoholic stimulation, which she used as an antidote for her grief at the death of her husband.

After this interview I went to work to gain the confidence of my patient, and to elicit from her a true history of her life in connection with the inroads of this terrible disease.

She said that until her marriage, some six or eight years previously, she was afraid to use wine or other stimulants of that kind, seeing its evil effects in the male members of her family; but her husband used wine at dinner, and his cellars were supplied with the finest imported liquors, to which she had convenient access, and the qualities of which she would sometimes test.

This unfortunate custom of her husband proved to be the Scylla of his wedded life, and the Charybdis upon which her bright young life has been wrecked. I learned from others, that before his death this contagious disease, the germs of which were latent, and which existed, I have since learned, in most of the other members of her immediate family, was developed to such an extent as almost to make an irreparable breach between them, and would probably have done so but for his early death, which was, however, in no way due to dissipation or over-indulgence. This gave her unrestrained license to feed the disease until it had produced the deplorable condition in which I found her.

Since she has been under my care, I have never seen more honest and vigorous efforts made to accomplish an end, than she has made to rid herself of this fearful curse. She is perfectly happy and contented if it is not about her, and she knows she cannot get it; but if it is in the house and she knows it, or if she passes on the street a place where it is kept, even a saloon, and thinks she can get it, she will often make the effort.

With all this burning, this terrible thirst for strong drink, she is a perfect lady, and when under its influence, her deportment shows the intuitive qualities of the lady. She will weep over and lament the terrible spell that is upon her, as if she had murdered her own beautiful little daughter.

She has a brother who is an excellent, sober citizen as long as he remains on the plantation, but whenever he goes from home, and meets with convivial friends, he has no control over himself whatever. That inebriety is oftentimes a disease —*a terrible disease*—and its victims should be greatly pitied rather than condemned and despised, I do not for one moment doubt. The great problem to solve in connection with this subject is, What is the remedy?

INVERSE TYPE OF TEMPERATURE IN TYPHOID FEVER, WITH A REPORT OF TWO CASES.*

Temperature Peculiarities in Epidemics, with a Report of Seven Cases in One Family.

BY W. C. HOLLOPETER, M. D.,
Of Philadelphia.

The classical investigations of Wunderlich, Thierfielder, and Traube, have done much to simplify the study of fever, and by their deductions they have rendered it possible for us to differentiate typhoid from all other continued fevers by its temperature alone. This universal tendency to refer a given symptom to an established, or partially established, law, has done much to lessen the interest of individual work; for those cases marking the exception are, as a rule, looked upon as complications, and slight causes are frequently brought forward to explain the apparent departure from the established rule. Dr. J. C.

*Read before the Philadelphia County Medical Society, November 26, 1884.

Wilson, in his admirably-written work on "The Continued Fevers," tells us that "marked deviations from the typical course of the temperature are always due to special causes. These causes, in many cases, cannot be discovered by the most searching investigation. On the other hand, upon inquiry, clinical facts of importance are often discovered, and it is therefore the duty of the physician, in every case when marked deviations occur, to make diligent search for their cause."

I enunciate a well-recognized fact when I state that every physician in general practice has had cases of typhoid fever where the temperature record has been irregular, when, at the morning or the evening visits, the thermometer has registered the same, or has shown some unusual feature in the evening exacerbation, or morning remission, departing in some unsatisfactory manner from the gracefully-arched curve of Wunderlich.

It has frequently been my lot to treat cases of fever having every symptom of typhoid, yet not responding to the well-marked type of temperature, as described by Wunderlich. For a long time it was very difficult to assign any cause for the variation, although it is natural for complications to disturb the rule, especially when we anticipate a typical curve in the temperature chart.

Dr. Wm. Pepper has stated, in a recent clinical lecture, that "it was the exception, and not the rule, to find a typical case of typhoid fever." Although every symptom may be uncertain, or even frequently wanting, in some cases of typhoid fever, yet I believe the temperature, the peculiar form especially, remains the most constant factor. and, as Grissinger states, it "generally controls the situation."

During the last seven months, I have had under my care a case of typhoid fever in which the temperature record corresponded to the "inverse type," as described by Traube.

Bäumler, in drawing attention to this unusual character of the temperature, states that, in the great majority of cases, the daily fluctuations follow the rule of health, the exacerbation taking place in the evening; we sometimes meet with cases where this order is reversed, the rise taking place in the morning, and the remission occurring in the evening.

This "inverse type," so named by Traube, of the daily fluctuations of a febrile temperature, has been observed in some rare instances in typhoid fever.

I have been unable to find any additional reference to this unusual type of temperature in the systematic treatises on fever; Liebermeister or Murchison do not mention it in their works, nor have I been able to find any clinical reports bearing on the subject, in any of the medical journals.

The clinical notes of my case are as follows:

Frank M., aged 14, thoroughly healthy parents, was taken ill May 15, 1884. My friend, Dr. Schoales, being the family physician, was sent for. The doctor was indisposed at the time, and I was requested to take charge of the patient. I found that the boy had been sick for two days, a slight chill occurring three days previous, and ever since he had been feverish, restless, and stupid; he had refused food and complained of headache; he had also slight nose-bleed and loose bowels. The history of the case was not unusual, having very well-marked typhoid symptoms, and was of interest in the character of the temperature alone, which was as follows:

	A. M.	P. M.	PULSE.
May 15	102⅘°	102°	100
" 16	104	103⅖	108
" 17	103½	103	108
" 18	103⅘	102⅖	112
" 19	105⅖	104	116
" 20	104⅗	101⅖	96
" 21	103⅗	102⅘	108
" 22	100	102⅕	96
" 23	99⅘	99	96
" 24	100⅘	100	96
" 25	101⅗	101	96
" 26	101⅘	101	100
" 27	98⅘	99⅕	100
" 28	100	99⅖	100
" 29	100⅕	99	100
" 30	101⅗	99	98
" 31	101	97⅖	98
June 1	100⅘	99	100
" 2	98	98⅖	98
" 3	98⅖	97⅘	98

In this case the boy had been complaining for a few days, according to the statement of the parents, before advice was called in. How much longer he had been ill we are unable to state, but, judging from the elevation of the first temperature (102⅘°), the case was evidently well on in the first week.

The exacerbation recurring so regularly in the morning, and the remission taking place as faithfully in the evening, caused me to watch the case with unusual vigilance. We could hardly be mistaken in the character of the fever—Dr. Schoales subsequently visiting the case with me frequently and corroborating the diagnosis; the stupid and listless countenance, the distended and tympanitic abdomen, the rose-colored spots, few, but constant throughout the illness, the gurgling in the lower portion of the abdomen, the loose

bowels, the nose-bleed, the deafness, all conjoined to render the diagnosis certain. Then the duration of the illness, while not very severe, extended over four weeks, which corresponds to the average duration of uncomplicated typhoid fever.

The treatment of the case was such as to have but little effect on the temperature, except to lower it; diet exclusively of milk and milk food; the recumbent position faithfully maintained; large and well-ventilated room, thoroughly disinfected. No drug was used likely to influence the fever, with the exception that, during the prevalence of the highest records, thirty grains of quiniæ sulphatis were exhibited in ten-grain doses, two hours apart, during the night. This was ordered on three successive evening visits. Cold-water sponging of the body was continued frequently as long as the temperature remained above 102°. We were unable to discover any complications whatever, in fact there were none; no bronchial irritation, no disturbance of the alimentary tract. The course of the fever was uniformly regular, the various symptoms occurring in their usual order, and the whole phenomena of the fever convincing as to its character, except the very important factor noticed in the *inverse type* of temperature.

The want of uniformity in the temperature record of the case just noticed, recalls the facts in a patient I had under my care nearly three years ago. The clinical notes recorded on the back of my temperature sheet at the time are briefly as follows:

Walter, æt. 7, was a well-developed boy, and the youngest in an exceedingly healthy family. The mother informed me that the boy had commenced to manifest a disinclination for food and play five days before any trouble was suspected. I was therefore called in on the evening of the fifth day. I found the little fellow quite delirious, with a temperature of 103⅖°, a full pulse of 130, respirations 26, face flushed and apparently swollen, eyes congested, skin dry and hot, bowels confined. Ordered a fever mixture.

In the morning, temperature had fallen to 100⅕°, pulse 100. The patient had relapsed into a quiet sleep during the early morning hours. The skin had become moist, On a more careful examination I found the abdomen tender, somewhat tympanitic and distended. The mother stated that there had been during the past ten days occasionally slight nose-bleed. The bowels showed a disposition to be free, yet, while not constipated, they had not been open regularly every day, now one or more free movements occurred daily. The third day, end probably of first week, if not more, the temperature, with a single exception did not go above 102°, but had a gradual decline. The interesting feature was the morning record, which was higher than the evening. This unusual feature continued for twelve days, the amount of variation was from one to one and a half degrees.

On the twelfth day, about the twentieth of the attack, the morning temperature reached 103°, without any other unusual symptom, after which it changed and ran as a typical case of typhoid fever in convalescence: morning 100°, evening 102°; morning 98⅘°, evening 101⅖°, etc.

The downward curve was thus continuing uninterruptedly until the seventeenth day, when the temperature ran up to 102° again; following this rise, the morning record marked 98°, and an intestinal hemorrhage of over four ounces of dark blood, following an unusually large fæcal movement.

The thermometer never registered a temperature after this above 100°. The case made a good recovery, convalescence slow. In this case we had a temperature curve closely following an ordinary typhoid fever chart, with the unusual exception of the twelve days of *inverse type*, with no discoverable complications to explain the cause.

I have not deemed it expedient to enter into an accurate analysis of each and every symptom of the foregoing irregular cases, knowing it to be exceedingly burdensome, yet I hope that I have sufficiently outlined the general features of typhoid, the phenomena of which are so constant as to make a diagnosis practically certain.

I wish now to present the salient points in a group of seven cases, occurring in the form of an epidemic in one family, in which the victims followed each other to bed in rapid succession, four of whom suffered very severe and prolonged relapses. All, however, eventually made a good recovery. It is not my intention to narrate these cases as especially unique or exceptional; but as taking place under one roof, and springing from one well-recognized cause, the variation in the temperature record alone became an interesting element of study.

The fever occurred in a very healthy German family; the parents, as well as the children, were free from predisposing weakness.

Case 1. Mary, æt. 13, was the first to take sick. I made my first visit to her December 6, when I obtained the following history: The patient had been complaining, for nearly a week, of weariness, chilliness, aching in limbs, back, and head,

loss of appetite, and a general disinclination to any physical exertion. I found her at 12 m., with a temperature of 104⅘°, pulse 112, skin hot and dry, puffiness around the eyes, with an injected conjunctiva, face dark and flushed. During the day, had diarrhœa, with vomiting. At 8 p. m. of same day, vomiting (continuing) of thick tenacious mucus, tinged with blood and bile; bowels were opened seven times during the afternoon. Since my morning visit, the girl has had low muttering delirium, but can be aroused by speaking in a loud voice. The back-ache was so severe as to merit especial mention, it being more pronounced than is usually found in bad cases of typhoid. The girl constantly complained of it during the first ten days. On the same evening, at 9 p. m., the thermometer had registered 105⅘°. In the morning it was 104⅘°; in the evening it was 105°. During the day and night, vomiting and purging continued nearly hourly—fifteen times, by the nurse's report.

At the end of the eighth day, the second day of my visiting, the back-ache continued violently, the hands being involuntarily placed in that region. Bowels continued loose, vomiting the same. Distention and tenderness of the abdomen decidedly marked, with gurgling in right iliac fossa, tongue heavily coated, dark and foul, sordes on teeth and lips. Vomiting discontinued on third day after taking her bed. Temperature 104⅘° in the morning, 105° in the evening; low muttering delirium, alternating with violent outbursts; three or four well-defined, rose-colored spots, at this date made their appearance on the abdomen. After the fourth day, probably the tenth or twelfth day of her sickness, the temperature did not run higher than 104⅘°, but did not fall below 102° until the eighteenth day. One very noticeable feature in this severe case was that, for two weeks, every other morning's fall was less or intermittent in character, while the evening exacerbation remained the same. During this period, there existed the wildest delirium, it being difficult at times to retain her in bed; bowels frequently moved involuntarily. The girl gained her strength very slowly; it was five weeks before the temperature approached normal, and it was ten weeks before she was able to leave her bed. She, however, made a good recovery.

(*To be continued.*)

—The city physicians of Atlanta, Ga., receive a salary of eighty-five cents a day, and furnish their own medicine.

NOTES ON THE TREATMENT OF EPILEPSY.*

BY CHARLES K. MILLS, M. D.,

Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic and College for Graduates in Medicine, etc.

His remarks applied chiefly to the medicinal treatment of epilepsy proper—grand mal, and petit mal. He did not intend to refer to the treatment of convulsive seizures due to tumors, meningitis, spinal disease, etc.

As to the curability of epilepsy, some apparently authentic cases of cure were on record. After looking over the subject, he could only recall seven cases of apparent or real cure in his own practice, private and hospital. In all of these the attacks remained away for from more than one to more than three years. Gowers mentions a number of cures, at least, cases in which seizures had not recurred for as much as four, five, six, or seven years. Several of these cases were children. Three of the seven cases alluded to by Dr. Mills were children. All observations as to the cure of epilepsy were necessarily imperfect. After a number of years, the attacks recur again. Although, however, the absolute curability of epilepsy might be doubtful, certainly great benefit from treatment is to be derived in most cases. It is wrong to such patients not to treat them.

He had used the following remedies, singly, three or four times daily, in a series of cases, during the last ten years: Bromide of potassium, grs. x. to ℥j.; bromide of sodium, grs. x. to ℥j.; bromide of ammonium, grs x. to ℥ss.; monobromide of camphor, grs. iij. to vj.; hydrobromic acid, f.℥ss, to f.℥ss.; iodide of potassium, grs. v. to ℥ss.; biborate of sodium, grs. xv. to xx.; chloral hydrate, grs. x. to xv.; oxide of zinc and valerianate of zinc, grs. iij. to x.; nitrate of silver, gr. ¼ to gr. ½; tincture of belladonna, ♏x. to xv., or extract of belladonna, gr. ¼ to gr. ½; extract of cannabis indica, gr. ⅛ to gr. ¼; fluid extract of cocculus indicus, ♏j. to iij., or tincture of cocculus indicus, ♏v. to x.; nitrate of potassium, grs. v. to viij. Other remedies, which he had only used in combination with some of the above drugs, were as follows: Conium juice, f.℥j., or fluid extract, ♏iij. to x.; tincture of digitalis, ♏v. to x.; sulphate of strychnia, gr. 1/40 to 1/30; Fowler's solution of arsenic, ♏ij. to v.; fluid extract of ergot f.℥j. to f.℥ij., or extract of ergot (Squibbs), grs. iij. to vj.; iron, cod-liver oil, and quinine.

*Read before the Philadelphia Neurological Society.

The bromides were certainly the best remedies, and the bromide of potassium, in his opinion, stood at the head of the list. The bromide of sodium came next best to the bromide of potassium. He thought the bromides affected the nerve centres directly. The mixed bromides were better, usually, than any one of them used singly.

The bromides could be advantageously combined with other drugs. The combination which he had found, on the whole, the best for long-continued use was, bromide of potassium, grs, xv; bromide of sodium, grs. xv; solution of the arsenite of potassium (Fowler's solution), ℥ij; conium juice, f. ʒss, or the fluid extract of conium, ℥iij to v. This was generally made up with syrup of orange and some bitter infusion. Another good combination, mentioned also by Gowers, was the bromide of potassium and tincture of digitalis. It was only especially valuable in cases complicated with weak heart or mitral diseases. Monobromide of camphor had no advantage over the bromides. Hydrobromic acid was efficient in very large doses, but so much water had to be given with it that the amount to be swallowed was appalling to the patient. It sometimes irritated the stomach. Borax was not of established value, but helped a few cases temporarily. He found the iodide of potassium, unless especially indicated, had little value used alone in the treatment of epilepsy. Chloral hydrate is not of much value when given alone, but with the bromides, in cases uncomplicated with cardiac disease, sometimes makes a useful combination. Trousseau's belladonna treatment had been used without noteworthy success. Cannabis indica was not to be depended upon. He had tried cocculus in six cases at the Philadelphia Hospital. None improved, and four were made worse by its use, one of the four becoming insane while taking the drug. At the request of Drs. Reichert and Hinsdale, he had used the nitrite of potassium in seven cases. Of these, only one seemed to be benefited, and some were made worse by its use. When the bromides had to be stopped, the zinc salts or the nitrate of silver were the best substitutes; but they could only be relied on for a short time.

The way to treat epilepsy, in his opinion, was to simply have a plan of treatment, and carry it out over a series of months or years. He would, for instance, first put a patient upon a single bromide, say fifteen grains three times a day, to be increased until a decrease in the number and severity of the paroxysms was produced. He kept him upon this perhaps for a month. He then used the mixed bromides, or some combination of bromides with other drugs, preferably the bromides, arsenic, and conium prescription. He watched the condition of the patient, and, if necessary, put him on cod-liver oil, quinine, or iron. With reference to nitrates, bromates, etc., he said that there was probably some chemical or chemico-physiological reason for inefficiency. The *ites* and *ates* would probably *never* give as good results as the *ides*. Dr. Mills believed with Dr. Pepper (Med. and Surg. Reporter, January 12, 1884), that close attention should be paid to every point in the daily life of an epileptic—to diet, rest, and hygiene—but he did not, with his present experience, believe that a genuine case of thoroughly-developed epilepsy could be cured, or even greatly benefited, without drugs. Harm, however, might be done by over-use of drugs.

Among the surgical and external means of treatment he had successfully used, were, excision of cicatrix, removal of neuroma, actual cautery, and blistering to the neck or head. He said he did not use counter-irritation to the scalp, but was a strong believer in the actual cautery, used after Brown-Séquard's method, to the nape of the neck.

Hospital Reports.

NOTES FROM THE PHILADELPHIA HOSPITAL.

(Specially reported for the Medical and Surgical Reporter.)

Service of Dr. W. H. Parrish.

December 13.

The Management of a Miscarriage.

Dr. Parrish presented to the class a woman who had been brought into the hospital one week before, with the history of a miscarriage. She was a reliable married woman, whose testimony could be believed. She gave the history that she was four months pregnant, when, going about her household duties, she received a blow on her abdomen, which was the exciting cause of the miscarriage. She did not go to bed either before or after the escape of the fœtus; she broke the cord herself, and continued about her household duties for three weeks with the placenta still in the uterus. She was *not* attended by a physician. During this time she had aches and pains, but very little hemorrhage. Three and a half weeks after the miscarriage, the pains became much more severe; there was considerable hemorrhage, and she was obliged to take to her bed, when she was brought into the hospital. After admission, the hemorrhage became so severe that her life was, for a time, in danger. This was controlled by a tampon saturated with Monsel's solution, placed in the vagina—*not introduced into the cervix*—where it was left for two or three days.

When Dr. Parrish saw the patient, her temper-

ature was 102°. Believing that there was something in the uterus, he removed the tampon and found old clots, undergoing decomposition, in the fundus of the vagina. The os uteri was patulous, and upon introducing his finger, he felt something in the uterus, which he concluded to be either placenta or old clots. The patient was then etherized, and while the uterus was pressed down with one hand on the abdomen, two fingers of the other hand were introduced, and the foreign body, which proved to be the placenta, was removed. After this, the uterus was injected with hot water (112°–115°), which temperature could be raised if the patient is etherized. He also used an injection of corrosive sublimate, 1 to 2000. The patient was then put to bed, without any special treatment, for a few hours. Within twenty-four hours the temperature fell to 99°; there has been no pain, no offensive discharge, and the patient is doing well. The lecturer considered that this case teaches us that the placenta at the fourth month can remain in the uterus for some weeks without producing serious symptoms, *but that it will produce serious trouble before it comes away.* He considers it criminal to let the placenta remain until bad symptoms develop, as has been taught by some authors. As an expert, he would call such action *malpractice.* He related the case of a woman where the placenta was left after a miscarriage. Four weeks subsequently, she was seized with severe hemorrhage; but even then her attending physician failed to remove the decomposing placenta. Four days later, Dr. P. was called in consultation; the woman was moribund; the placenta was removed, but the patient died.

The lecturer considers no practice so fallacious as the use of *drugs* for the purpose of emptying the uterus, more especially of a placenta. The weakest portion of this organ is that to which the placenta is usually attached, the strongest being that which includes the contracting fibres of the cervix. Hence when we give ergot, we close up the cervix and incarcerate the placenta; and we also render the introduction of the finger, for purposes of examination, next to impossible. He would not leave the placenta in the uterus more than an hour after a miscarriage.

Puerperal Mania.

Case 2. Woman, aged 38, admitted December 3; had been in labor for 24 hours; two hours later was delivered of a male child weighing eight pounds. This was the third pregnancy; all previous ones normal. There was some hemorrhage (slightly more than normal, but not severe), which ceased when the placenta came away. She seemed heavy, stupid, and disinclined to answer questions. For some days her physical condition was good, but on December 8 her temperature rose to 100½°. There was some abdominal tenderness; no chill. Her bowels were moved and quinine given, with poultices to abdomen. The temperature fell. On the evening of the fifth day she had a convulsion, which yielded to chloroform inhalations. During the night she was given 60 grains of bromide of potassium and 20 grains of chloral. On the sixth day her condition is not improved, and it is noted that she is becoming more violent. Hydrobromate of hyoscyamin was used hypodermically without any appreciable effect. Her urine was found to be alkaline, and there was no albumen. Upon inquiry it was found that a brother of this patient has been an inmate of the insane department of this hospital since 1862. The woman herself had been a respectable married woman, living happily with her husband for some years; the latter had recently died, and she had become this time illegitimately pregnant. She had entered the hospital without the knowledge of her family, and her clouded mental state prevented the gathering of her family history. These facts Dr. P. considers, combined with the history of insanity in her family, would account for the mania. The association of Bright's disease and puerperal mania are rare, mania being notably absent in the puerperal form of this disease. Puerperal mania is not necessarily maniacal in its character, it may be melancholic, but it most commonly shows a tendency at times to maniacal excitement. This woman at times becomes enraged, though she is generally quiet and under the influence of illusions and delusions. In this case the prognosis, so far as mental restoration is concerned, is not favorable, owing to the family history. There is, of course, no danger to physical health nor to life. When there is no inherited taint, these cases usually recover entirely in from two to six months. If the mania partakes of a hypochondriacal nature the prognosis is bad, for these cases rarely get well; they are apt to have strong suicidal tendencies, and must be carefully watched. In the majority of cases, opium is contraindicated, because it increases the quantity of blood in the brain and augments the excitement; even if it does produce sleep, the patients are apt to awaken in a state of greater excitement than before. When there is depression or melancholia, or if there be associated peritonitis or active pelvic inflammation, opium may be administered; but these are the only conditions in which Dr. P. would consider its use justifiable. He much prefers chloral; giving *one full dose* at bedtime, instead of smaller doses repeated. The first night he would give ten grains of chloral and forty grains of bromide of potassium in a single dose at 9 o'clock. If this does not suffice, he would give the next night thirty grains of chloral, but he would never exceed this dose; though if the desired effect is not produced, fifteen grains may be given in four hours. During the day he uses the bromides. In puerperal mania it is always well to look after the kidneys and bowels as well, indeed, as for latent disease all over the body.

Dr. Joseph Neff.

Uræmic Coma.

The lecturer brought before the class a case, not because, as he said, he "knew so much," but because he "knew so little" about its nature, and he desired to make a diagnosis before the class. The patient was a colored girl who had been brought into the house in the ambulance in a comatose state, having been picked up somewhere on the highways. There could be obtained absolutely no history, and Dr. Neff proposed, by a process of exclusion, to endeavor to reach a diagnosis. The first thing noticed is a general muscular twitching, not confined to either side. Sensa-

tion is not lost; indeed, there is rather hyperæsthesia of the surface. The pupils are normal, and respond to light. There is no paralysis of the arms or legs, the mouth is not drawn, there is no ptosis, and reflex action is perfect. If this was a case of *apoplexy*, we would be almost sure to have paralysis somewhere, and stertorous respiration, while muscular tremor would be unusual. It might be a case of *syphilitic gumma* of the brain; but the glands are not enlarged, and there are no suspicious scars on any part of the body. In *hysterical coma* you can bury a needle in any part of the body without response. In *catalepsy* there is rigidity of the muscles, the eyes are usually open, and the limbs remain fixed in whatever position they are placed, no matter how awkward the position may be. The patient's pulse is now 92; it was only 80 when she entered the house. The lungs are free. There is considerable albumen, and Dr. Neff is inclined to call this a case of uræmic coma, though one important point is wanting; in uræmic coma the temperature is generally below normal, while in this case it is 101°. However, he accounts for the high temperature by supposing that the girl must have been very sick for some time (some days at least before her admission), and that the constant muscular twitchings, along with the want of food and care, could produce this elevation. There can be no effusion in or on the brain, for there are no signs of compression.

Treatment.—The bowels must be opened freely. She must be made to sweat by wrapping her in blankets, and surrounding her with bottles of hot water wrapped in cloths wrung out of water. Give pilocarpine hypodermically, $\frac{1}{16}$ to $\frac{1}{4}$ of a grain. When she can swallow, give calomel in small and repeated doses. If she gets worse use croton oil.

Dr. John M. Keating.

December 17.

Cerebral Pneumonia.

Patient, little less than a year old, has been in the house for three months. The parents are apparently healthy, but have already lost three children from some brain trouble. On November 29, the child became restless and cross, with a temperature of 100°. It was given a simple fever mixture. The next day the restlessness increased, and it was rolling its head; but there was no convulsion, no cough, and the eyes were normal. Quinine was ordered by suppository, with mustard foot-baths, and the fever mixture continued.

On December 1, the temperature was 104$\frac{1}{5}$°. General baths were now ordered, and to the other treatment, bromide of potassium was added.

December 2, the temperature was 103$\frac{2}{5}$°; there was vomiting, great restlessness, and hyperæsthesia. Some cough was now noticed for the first time, for which carbonate of ammonia, syrup of ipecac, and paregoric, were ordered.

On December 3, some dullness was noted at the apex of the left lung. The respirations were quick and short, and the pulse very rapid, out of proportion to the temperature. Here, then, we had a case of pneumonia, giving rise to and ushered in by the cerebral symptoms, that would be very apt to mislead the physician. Cerebral pneumonia is usually located at the apex of the lung and confined to one side, and it is often impossible to discover it until consolidation has taken place. The treatment, in addition to that already described, consisted in the use of jacket poultices, then a *cotton* jacket, and quinine by the mouth, in syrup of yerba santa, when the suppositories commenced to irritate the bowels.

In children's practice, we should always study the temperature. When we find it ephemerally elevated, it is of no moment; for any slight cause, such as indigestion, or catarrhal troubles (so common in this abominable climate), or slight restlessness, or, indeed, anything upsetting the nervous system, may run the temperature up to 104°; but when we have it persistently elevated, we know that there is some inflammatory lesion of a more or less serious nature. This is an important point, because parents are apt to worry and get very much frightened when the baby has "fever;" so it is well to bear this distinction in mind.

To reduce high temperature, when due to some lesion, we can employ hot foot-baths and quinine, by suppository, when the stomach is irritable, using always the sulphate. He gives quite large doses, and that persistently; that is, he would give 1, 1½, or even 2 grains every 3, 4, or 5 hours until the temperature is reduced and kept down. We may use a full warm bath, but be careful not to have it too warm, for it does sometimes happen that babies are dropped into water hot enough to scald them. Wrap the child in a blanket, gently lower it into the water, and keep it there for ten or fifteen minutes. We do not want a shock. This warm water will draw the blood into the cutaneous capillaries, where it will be cooled by the subsequent reaction; just as the reaction from cold water will make us warmer. While the child is in the bath we may apply cold to the head. When you suspect that the high temperature is prodromic of a specific fever, the liquor ammonii acetatis is an excellent drug with which to combat it. In cases such as the one described we are very apt to suspect scarlet fever; and the treatment just mentioned will be very appropriate, and will aid materially to bring about the eruption. The medical treatment of high temperature is very simple, but exceedingly important. High temperature, thermic fever, sunstroke, or whatever you may choose to call it, can cause death in a child as well as in an adult. He has never used *cold* water with children, though he has with adults. It is recommended by some authors among children, but he considers it dangerous, and besides does not think it necessary to use very cold water; water *comparatively* cold, that is when the temperature of the body is 104.5°, water at 90°, 80°, or even 70°, while not *absolutely* cold will be *comparatively* so, and will answer every purpose without being dangerous. Parents will oftentimes object to putting a sick child into a bath-tub, considering such a measure harsh. To overcome this scruple, you can place two chairs face to face and lay a blanket over them. Saturate this blanket, and placing the child on it, cover with another blanket; in this way we get constant evaporation. Sometimes the fear of the bath may be allayed if the parents know that it is medicated, when it seems less

harsh; so that we might put a little vinegar in the water.

Diet.—In these cases of high temperature, and particularly in the continued fevers, the digestive juices are nearly absent, and the mucus in the bowels so interferes with their action that ordinary milk cannot be used. Whey is recommended by some, but Dr. K. does not consider it very nourishing. Condensed milk he considers to be a mighty poor food. Pancreatized milk, in his judgment, has solved the much-discussed problem of the artificial feeding of children, for he does not believe that it will ever be possible to find a food more perfectly adapted to the stomachs of children, and indeed he does not think that there is any occasion to ask or look for a more suitable food. To prepare this milk, he operates as follows: In a gill of water he dissolves five grains of extractum pancreatis; to a pint of milk, at a temperature of 110, he adds this solution. The pancreas is first put in water, because it contains a curdling ferment, that is weakened by water. It is not necessary, as some have stated, that the milk and pancreatine should be allowed to stand for some time. The baby's bottle can be filled with milk, put in warm water to raise the temperature, the solution of pancreatine added in proper proportion (the gill to the pint as already stated), and used at once.

DR. H. C. WOOD.

The Hygiene of the Aged.

In order to illustrate his remarks on the care of the aged, Dr. Wood presented to the class two cases, the first one of *senile gangrene* in a man aged 77; the second, *senile dementia*. After eliciting their histories, he sent them out of the room, with the very wise remark that all you can do for these cases is to make them comfortable while life lasts, and he then went on to make a few remarks about how to make such life comfortable, and how to retard as long as possible the downward course of senile decay. He relates the history of an old man, who had come to him ten years ago and told him that while he could not expect to live forever, he yet wanted to live as long as possible, and asked Dr. Wood to endeavor to prolong his life; he undertook the task, and the old man is alive to-day, at eighty-five years of age, the lecturer considering him altogether *too good a patient* to let die. Dr. Wood tells us that very many old men die of exposure, which after all is but a relative term, since a young robust man may wade half a day in the water for partridges, or lie out in the biting cold in a sink for ducks, and it will not constitute exposure; whereas the draught from an open door may mean fatal exposure to the waning energies of an old man. Dr. Wood believes that every person 75 years old, or less, if their vital powers are failing, should wear a *buckskin* jacket, which he very much prefers to flannel or silk. He thinks that nothing will compare to it to prevent the little chilling of the surface, which means a dangerous internal congestion in the aged. Old persons should spend many hours in bed. Their food should be light, but nutritious, using meat sparingly, and relying chiefly upon milk, as they did at the other end of their journey through life. Especially must they guard against exposure to high winds, for this cause can claim its ten thousand victims among the aged, when dampness and its results must be satisfied with one thousand. Especially are high winds to be avoided when the body is heated. Dr. Wood quoted the case of the late Rev. Dr. Beadle, who, coming out from his warm church on a windy day, had hardly walked a square when he was seized with great oppression about the chest, and died very shortly from congestion of the lungs. Alcohol and opium are useful agents to prolong the life of the aged; if you can make your ancient patient an opium-eater you will prolong his life; but you must order the opium carefully, and it is just as well not to let him know what he is taking. Dr. Wood has a patient who has been taking opium suppositories at night for ten years, commencing with one grain; they now contain two and a half grains, and he takes a little morphia through the day. Every old man ought to take some form of alcohol at meal time; by studying the digestive processes we can determine what form will be the best. It is very essential to stop any acute attacks in old persons, and in five cases out of six this can be accomplished by putting them to bed and using opium.

MEDICAL SOCIETIES.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Discussion on Epilepsy. (*See page* 104.)

The discussion was opened by Dr. E. T. Reichert. He said that the efficacy of the bromides was certainly not due to the bromine, for bromide of potassium is the best of the bromides, and it contains less bromine than any of the others. The amount of bromine in the chief bromides, as given by Gowers, is as follows:

Bromide of ammonium	81 per cent.
Bromide of potassium	67 per cent.
Bromide of sodium	77 per cent.
Bromide of lithium	92 per cent.

All the bromides act alike, but with varying degrees of efficiency. The bromates, nitrites, etc., are not as useful as the bromides. A certain line of similar chemical salts seem to give uniform physiological and therapeutical results.

Dr. Guy Hinsdale said that, in regard to the cases in which Dr. Mills used the nitrite of potassium, some four years ago, one was benefited, some remained the same, while others were apparently made worse by its use.

Dr. Wharton Sinkler wished to know if any of the members of the society had used hyoscyamus, and with what results. He said that Althaus, of London, reported cases in which tincture of hyoscyamus had been used successfully, in doses of from one, two, or three drachms. He said that he had reported one case of epilepsy which had been greatly benefited by cannabis indica, after the bromides and other remedies had failed.

Dr. H. M. Wetherill said that, in his experience, the bromide of potassium was the best remedy. He said he had never tried the tincture of hyoscyamus. He had never seen a case of epilepsy entirely recover.

Dr. F. Dercum said that his experience was

summed up in the statement that he had found the bromides the best.

Dr. Morris Lewis spoke of the cure of a child, three years old, at the Episcopal Hospital, in which he could obtain no results with the bromide of potassium. The seizures continued, and were worse, if anything. He then resorted to bromide of ammonium, and with immediate good results.

Dr. J. H. Lloyd said he thought that in cases of epilepsy attention to the digestive functions and to sleep were highly important. He called attention to the observation of Dr. Radcliffe, that epileptics have a tendency to over-eat and to sleep too much. In his own experience he had found that when constipation was present the seizures were likely to be more frequent and severe. Dr. Radcliffe and other English physiologists seemed to prefer comparatively small doses of the bromides long continued. Dr. Lloyd believed the combination of three bromides with the iodide of potassium to be one of the best in the treatment of epilepsy.

Dr. A. J. Parker said he believed we could not say that the effect of a drug like bromide of potassium, bromide of sodium, etc., was due either to the bromine, or potassium, or the sodium, etc. Each of these salts is an individual drug, each molecule of which has its own form of motion. Bromine is a substance with its own peculiar molecular condition of motion. Potassium, similarly, has its own motion. Bromide of potassium is the resultant of the two motions. Certain members of the same chemical families, as the bromides, iodides, and chlorides, would seem to go together in therapeutical efficacy, due to similarity of their forms of molecular motion. At any time, we may expect, however, to find wide differences, since our chemical equations simply represent an idea of structure, and tell us nothing concerning the form of molecular movement; and therapeutic effects must certainly depend more on the energy and form of motion than upon any other qualities.

Dr. E. T. Reichert made a few remarks on the use of *Hydrobromic Acid and the Bromides in Sea-sickness.*

He said, while crossing the ocean, he had the opportunity of studying the effect of hydrobromic acid and some of the bromides in sea-sickness. Hydrobromic acid was effectual, but had to be used in such large doses that, owing to the dilution with water necessary, the bulk to be taken was excessive. The bromides were, therefore, he thought, to be preferred. Bromide of sodium, in large doses, was effectual in one bad case. He believed that all the bromides were good.

Dr. J. M. Taylor spoke of the use of *Nitrite of Potassium in Angina Pectoris.*

In an aggravated case of angina pectoris, he had obtained very good results with nitrite of potassium. The patient had been suffering for over a year with paroxysms of increasing intensity, until death seemed imminent. After giving the nitrite of potassium for four weeks, the patient recovered. Nitrite of amyl was used sparingly to control the paroxysms.

The Mullein Plant in Pretubercular and Advanced Phthisis Pulmonalis.

Dr. F. J. B. Quinlan, who has been advocating this drug for some time, read a paper on the subject before the last International Medical Congress, which we reproduce from the *Dublin Jour. Med. Science*, September 1, 1884:

In the collection of ancient Irish manuscripts contained in the library of the Royal Irish Academy are several medical treatises in which the mullein plant is strongly recommended in pulmonary disease. In fact, the first word of its Celtic name, *cumeal mhuipe*, means "good for pulmonary complaints." From time immemorial the Irish peasantry have regarded this plant as an unfailing cure for consumption; and thus it is that an herb, which in England, France, and German is a mere wild weed, is in Ireland carefully cultivated on a very large scale. It is in constant demand, it is advertised in all the journals, and, in fact, forms an article of ordinary commerce. There are five mulleins, all belonging to the natural order of scrofulariaceæ; but the one in question is the verbascum thapsus, or great mullein, which is known in France as the *molène bouillon blanc*, and in Germany as the *kleinblumiges wollkraut*. It is a hardy biennial plant, with a strong stalk from half a metre to two metres high, with thick woolly and mucilaginous leaves, and a long flower spike with numerous yellow flowers, the smell of which is not disagreeable. The best results are obtained with the green leaves, which can be procured during seven or eight months of the year; but excellent effects are produced by the dried leaves also. By cultivation under glass the mullein can be had fresh during the winter; and this is important, as will presently be seen.

The method employed by the Irish peasantry is to take one hundred grammes of the fresh green leaves (or about thirty of the dried) and place them in rather more than one litre of fresh cow-milk. This is brought to a boil, and allowed to stand for ten minutes. The hot fluid is then filtered, is slightly sweetened, and is drank while warm. This whole quantity is taken twice or, in some cases, three times a day. It has a soothing pectoral effect, and, after a little time, is much liked by the patient.

Although in such popular repute, and in such extensive use, the mullein is not in the pharmacopœia, nor was it regularly recognized by the medical profession. It appeared to me that it would be well that the matter should be properly

investigated, and accordingly, during the last two years, I have treated a series of cases of pulmonary consumption in all its stages—127 in number—with the mullein leaf solely, with one trifling exception, which I shall presently notice. This procedure gave the most unbounded satisfaction to the patients, who implicitly believed in the remedy, and co-operated zealously with me in its use. Previous to commencing treatment each patient was carefully weighed, and this weighing was repeated every week, with great attention to uniformity of conditions as to time, clothing, meals, etc. The symptoms and physical signs of each patient were accurately noted, and the results tabulated. The conclusions to which I have arrived are as follows:

1. In the early and pretubercular stage of pulmonary consumption mullein has a weight-increasing and curative power greater than that of cod-liver oil, and nearly equal to that of Russian koumiss. It has been experimentally proved that this is due to the mullein, inasmuch as the milk alone fails to accomplish the same results.

2. In cases in which tubercles are well established, or cavities exist, the mullein has a great power in relieving cough. In fact, such a patient taking it requires no mixture at all, and every practical physician will recognize the great boon which this power confers on the phthisical sufferers, whose stomachs are often hardly able to receive sufficient alimentary sustenance. Indeed, the mullein milk is looked on by them more as a food than as a medicine. In persons of very feeble digestion, heaviness is often experienced after so much milk. This, however, can be completely relieved by allowing the boiled mullein milk to cool down to 50° C., and adding a teaspoonful of Benger's pancreatic fluid. It should then be left under cover for ten minutes.

3. Phthisical diarrhœa is completely obviated by the mullein. This is, no doubt, aided by the milk, but also occurs when the mullein is prepared with water.

4. All the symptoms of pulmonary consumption can be combated by the mullein, except colliquative perspirations—over them mullein has no influence; and in my cases I principally employed the hypodermic injection of the atropia sulphate. This is the exception to the sole mullein treatment to which I have already alluded.

5. Mullein smoke applied directly to the respiratory passages has a great effect in relieving irritation and spasmodic coughs, and coughs in general. The dried leaves of the mullein are broken up fine, and are smoked in an ordinary pipe, either pure or mixed with a little tobacco to flavor them. Wheeler and Whitaker, of High-street, Belfast (Ireland),[prepare very elegant cigarettes for this purpose. These are of two kinds: (1) mullein, flavored with a little Turkish tobacco; (2) for those to whom tobacco is disagreeable, mullein, flavored with a little oil of cascarilla.

I now exhibit both varieties of these cigarettes, as well as specimens of the mullein plant.

Koumiss can be had only where the mare is a regular milch animal; because, for chemical reasons, the milk of the cow does not make proper koumiss. Cod-liver oil is very disagreeable to take, and the quantity which is taken in all civilized countries, notwithstanding the wry faces generally made while taking it, by patients of all nationalities, is the surest testimony of its merit. It is, in my opinion, inferior to the mullein milk as a weight-increaser. It does not arrest cough, and it often does the contrary of arresting phthisical diarrhœa. Lastly, it disgusts the feeble stomach very much—to such an extent that many patients are entirely unable to take it. In the whole course of my experiments I met no patient who could not take the mullein, and scarcely any who disliked it.

I will conclude this paper with two typical cases of the cure of two patients who were suffering from early but undoubted pulmonary consumption. Both these patients are now alive, and in robust health, and I visited both just before leaving Dublin.

Case 1. Helen S., aged twenty, single, a governess, residing in Dorset street, Dublin, suffered 18 months previous to her admission into St. Vincent's Hospital, from inflammation of the left lung. Her health fell away, she coughed, became emaciated, and the catamenia ceased. She had slight dullness over the apex of the left lung, and auscultatory phthisical signs. She weighed 110 English pounds. In five weeks she increased to 119 English pounds, all symptoms disappeared, and the catamenia returned during the treatment.

Case 2. Elizabeth B., aged eighteen, single, a dressmaker, residing in Gloucester street, Dublin, had been ailing for four months. She coughed, and once had slight hæmoptysis. She lost flesh, and the catamenia ceased. On admission into St. Vincent's Hospital, I detected slight dullness over the right clavicle, and stethoscopic evidences of early consumption. She weighed 90.25 English pounds. Soon after beginning the mullein treatment, the catamenia returned, and after six weeks of it she had increased to 102.75 English pounds, with evident recovery. She was now sent to our convalescent department in the country, when I directed her to get cod-liver oil and discontinue the mullein. For thirty-three days she took a tablespoonful of cod-liver oil twice and sometimes thrice daily, and increased 7.50 English pounds only. This was the more remarkable, as, while taking the cod-liver oil, she had the aid of fresh air, sufficient exercise, and an abundant diet, of which she took ample advantage.

The above two cases are typical of about fifty instances of early consumption in which complete cures were effected. It is worthy of remark that very young mullein leaves have a dangerous resemblance to young foxglove—so much so that I have known an experienced gardener to put a young plant of the latter into a mullein bed. Of course, as soon as the poisonous intruder grew a little he was detected and expelled. Full, or even half-grown mullein and digitalis are not the least like each other. Dr. Ernest Knowling, of Tenby, South Wales, England, reported to me a case where belladonna leaves got accidentally mixed with mullein, and produced serious but, happily, not fatal results. I saw myself the leaves and flowers of the belladonna which had been picked out of that parcel, and they were further identified by Mr. Holmes, Botanist to the Pharmaceutical Society of Great Britain. We investigated this case, and found that the mistake

arose from the highly reprehensible practice which prevails, even in some most respectable drug-stores, of allowing dried poisonous leaves to be lying about in the same loft with non-poisonous ones. No person, however inexperienced, could mistake fresh belladonna for fresh mullein; but when leaves are dried and curled up it requires an expert to distinguish many which, when green, are quite unlike. The above are the only troubles which have come to my knowledge connected with the use of a valuable remedy of which I solicit the consideration of this Congress. I feel that I lay myself open to much criticism in coming forward here to announce a specific even for early and pretubercular phthisis; for I am aware that many think but little either of cod-liver oil or koumiss.

The power of the mullein is soothing the downward path of the advanced sufferer is of lesser consequence; for, did it not exist, there are many other ways of accomplishing the same object. My only apology for the position I take is this—a high standard of ancient native culture perished in Ireland amid a sea of national woe; and, from my boyhood, I have seen the humbler classes of a whole nation cultivating, believing in, using, and paying for a remedy which elsewhere was, in modern times, regarded as a mere weed. It appeared to me that a whole nation using a remedy for centuries, and, no doubt, judging it by results, could not be wholly wrong. I approached the subject without any preconceived opinion, and had the result of my research been unfavorable, and the opposite of what it was, I had determined to announce it as such. All that I ask for this remedy from my esteemed colleagues here is to try it in a similar spirit, and I have no expectation of their taking any other course.

The History of Blood-letting.

In the *Med. Press*, Dec. 3, 1884, Mr. Brinton briefly sketches the history of blood-letting as follows:

"The first recorded case was one which occurred at the close of the Trojan war, and is referred to in the works of one Stephanus, of Byzantium. The origin of the practice was attributed by Pliny to the Hippopotamus on the Nile. The words of the translation of Philemon Holland (A. D. 1601) were given in their entirety. A short account of some of the views of Galen on the subject was given, and it was shown what opposition his views on the subject of blood-letting called forth, chiefly from the blind followers of Epasistratus, who preceded him by about 400 years. The change of practice which has recently taken place was shown to be due—1. To the discovery of chloroform, which, in many surgical cases, does that which before could only have been accomplished by copious depletion; 2. To a more inquiring mind, which began by trying the experiment of watching the natural history of those diseases which previously had been treated by bleeding according to tradition. The author disclaimed any such excuse for its discontinuance as that occasionally brought forward, viz., change of type of disease as well as of mankind. He would discuss blood-letting chiefly in respect of the treatment of uræmic, puerperal, and epileptic convulsions, apoplexy, bronchitis, dilatation of the right heart from valvular diseases, pneumonia, and thoracic aneurism. The utility of the practice in most of these diseases was illustrated by cases. With regard to uræmia, cases showed that blood-letting had a marked action in reducing the amount of albumen present in the urine. In one case the total amounts of albumen in the urine, of two periods of twelve hours, immediately before and immediately after venesection, were 75 and 30 grains respectively. Recorded cases also showed that it was often called for and successfully practiced in puerperal eclampsia. Two cases were brought forward illustrating this. In apoplexy it might be called for during the period of reaction, never before; the guide to the condition of the artery in the brain being the state of tension of the pulse of the wrist. Any lowering of tension of the arterial system might allow the formation of a clot in the ruptured artery and check the increase in amount of the effused blood. Allowing that in apoplexy there was cerebral anæmia, the only effect which a rapidly-increasing effusion of blood would have, must be increasing strangulation of the circulation of the parts near it, and limiting the effusion would tend to prevent increase of strangulation. In diseases of the valves of the heart leading to a dilated right ventricle, general bleeding, when other remedies had been tried and failed, was of signal service. In these cases the effect was simply mechanical, and an irregular and empty pulse was the indication for blood-letting. This application of blood-letting was quite in antagonism to older teaching, inasmuch as formerly it was practiced when there was an 'inflammatory' pulse, mainly with the object of limiting the inflammatory process. In some cases of pneumonia, when, about the time of the crisis, there were signs of a failing heart, blood-letting should be cautiously tried, as in cases of this kind the cause of the failure is obstruction between the right and left sides of the heart, leading to an impossibility of the right side drawing enough blood to fill the arterial system. Bleeding in bronchitis with the same object, viz., that of relieving the right side of the heart, was often necessary, and should be done without regard to the tumultuous and irregular action of the heart, as this was due to the causes mentioned above. In the treatment of thoracic aneurism, bleeding has undoubtedly prolonged life. A case was quoted in which a man had an aneurismal swelling on the front of the chest, absorbing the costal cartilages and ribs for fifteen years; he died at the age of sixty-five, having been bled over 160 times. With regard to local blood-letting by leeches, the indication for its use was pain, such as the pain in a dry pleurisy or in cases of perityphilitis. In conclusion, the precautions necessary in the operation were briefly mentioned, and it was pointed out that in many cases in which bleeding was necessary, the cutaneous veins of the arm were impracticable, owing to deficient circulation through the limb. In these cases the external jugular was always available."

An Unusually Severe Case of Syphilis Acquired Without Any Primary Sore.

The following unusual case is reported in the

Lancet, December 13, 1884, by Dr. Stenson Hooker:

"The subject of the case, whom I will call A. B——, is a medical man, aged thirty, practicing in a small country town where cases of acquired syphilis are anything but common.

"A. B—— has always led a strictly sober and chaste life. He was in his usual health in February last, when a gentleman's servant presented himself at the surgery to be treated for a thin, watery discharge from the urethra and nocturnal emissions. There was a very insignificent sore under the glans penis, so small indeed that it could only be called an excoriation. A. B—— examined this carefully, and resolved to leave it to take care of itself, the result being that it healed up in a fortnight. The other symptoms were treated, but not syphilitically, and the patient so far improved that towards the end of the month he ceased to attend. In about seven weeks after this, A. B—— began to suffer from very severe frontal headache, both night and day, but worse at night. This increased in severity, and soon partook of a constant stabbing, lancinating character. It was thought that he needed rest and change. No idea of the real nature of the case was yet suspected. Had he had a scratch on the finger, to say nothing of a sore, the true cause of the pain would probably have been divined: but he emphatically avers (and the averment may be implicitly relied upon) that for some years past he has not had any lesion of the skin in any part of the body, and has run no chance of being syphilitically infected, excepting by the servant mentioned above. He now went to the seaside, and a few days afterwards general periostitis of the skull set in, and was so aggravated that the whole head was a mass of nodes of the size of walnuts, the pain being most excruciating. At this time he was closely questioned by a medical friend as to any possible way whereby his system might have been poisoned with syphilitic virus; but after what has been said I need scarcely add that the malady could not be traced to a primary sore. General cervical cellulitis appeared next, with great enlargement of the post-cervical glands; there was now also (about six weeks after the commencement of the headaches) a lichenous rash which covered in a uniform mass the whole of the trunk and extremities; simultaneously with this the tonsils were badly ulcerated, and it was not till then that A. B—— could be got to acknowledge that he was suffering from any of the symptoms of that protean disease, syphilis. Iodide of potassium was now taken vigorously, and the pain gradually abated. He was at this time returning to his work, and on his way consulted in London one of the greatest authorities on this particular disease, the throat being still ulcerated, and the rash only beginning to fade. This gentleman told him that there was not the slightest doubt as to the nature of the malady, and carefully examined him for evidence as to primary sore, but none, of course, could be detected. Mercury-with-chalk pills were ordered, and under this treatment the throat rapidly improved and the rash disappeared by desquamation; but for the next twelve months A. B—— suffered from deep fissures and recurrent ulcerations of the tongue, with congestion of the ciliary vessels of the eye, and loss of hair.

"Now, I can most conscientiously aver that this medical man presented himself as a sad example of one in whom, in spite of all his symptoms, there had never been any primary affection; through what particular channel the poison was absorbed is still, and must, as far as I can see, remain a complete mystery; that he never had a chancre I can again most positively aver. A. B——'s patient, it should be said, returned for treatment, this time suffering from the same unmistakable syphilitic symptoms."

Caseous Pneumonia of the Entire Lung.

Before the Pathological Society of London (November 4, 1884), Drs. Lanchester and Hobson showed the lung and microscopical sections from this case. The patient died seventeen weeks after an acute attack of chest disease. The symptoms and physical signs were those of an empyema of the left side, including marked bulging and displacement of the heart to the right. Upon this diagnosis the chest was punctured in several places, and also incised, but with negative result. A drainage-tube was, however, inserted in the wound, which continued to discharge sero-pus to the end. A spontaneous opening formed subsequently at the seat of one of the punctures in the axilla, and purulent fluid continuously drained through this. The surgical treatment was strictly antiseptic. A few days before death, symptoms of tubercular meningitis came on. After death there was found to be no pleuritic effusion, but the whole of the left lung was solid, distended, and filled with dry, caseous material, which, however, had softened down and left a cavity in the superficial parts of the upper lobe corresponding to the axillary opening. The artificial opening simply led into a blind channel in the lower lobe. The right lung was studded with miliary tubercles. There were also tubercles in the liver, which was fatty, in the kidneys and spleen. There were tubercular ulcers in the small intestines. The microscopical appearances in the affected lung showed thickening of pleura, a decided but not uniform increase of the alveolar walls, and the alveoli stuffed with inflammatory products in which epithelial elements could only occasionally be traced. As far as the experience of the authors went, this case was unique. The sign which of all others was regarded by writers as diagnostic of *effusion* as distinct from *pneumonia*, viz., displacement of the heart and bulging of the chest walls, was present. The uniform consolidation and caseation of the entire lung, with an absence of a similar process on the opposite side, was also remarkable. The only cases which seemed at all parallel were those which have been described by Virchow, Wagner, and others, as syphilitic pneumonia in infants. The possibility of syphilis in their case seemed out of the question.

Dr. Goodhart had seen a similar case. It was mistaken for empyema and tapped. The whole of the left lung was converted into a solid mass, and there were tubercles. The disease was not rare in partial form; a solid cheesy mass was not uncommon in middle lobe of right lung. It cer-

tainly was not syphilitic; perhaps it was a diffused lympho-sarcoma.

Dr. Duckworth said that clinically and pathologically such cases were rare. Caseous invasion from the bronchial glands was not uncommon, but in this case the disease enlarged the lung and the chest wall. The clinical history was one of tuberculosis, he thought, a good account of the microscopical appearances.

Dr. Percy Kidd thought he had seen several similar cases; the question of tuberculosis might be settled by an examination for bacilli.

Mr. Butlin recalled two or three cases tapped without result, in which the lung was solid.

Dr. Angel Money had seen two cases.

Dr. West said that a mistake between solid lung and empyema was almost unavoidable. His idea was that the tubes were occluded by secretion, or they might be pressed upon by new growth, and the consolidation be thus produced. He thought that the naked eye appearances were those of sarcoma.

Dr. Lanchester said that they could exclude syphilis. The bulging and displacement of the heart was most unusual. The structure was very hard; notwithstanding the treatment, the lung did not break down, which was unlike caseous pneumonia.

Agoraphobia.

Dr. R. Prosser White thus writes in the *Lancet*, December 27, 1884:

In the wide field of scientific medicine, research and demonstration are gradually hemming in and contracting the circle of functional disorders, and the onus of causation is placed upon some unsubstantial coccus or some undefined catalytic action. Functional disorders, however, do exist, and are perhaps increasing, as is proved by the frequent usage of words expressing derangements without inflammation, or constant structural change, such as neurosis, neurasthenia, hysteria, hypochondriasis, etc., to which category this curious phase of nervous phenomenon, I think, belongs.

B. C., aged about thirty, a professional gentleman, of active intellectual habits, whose previous health was good, and whose family history shows no predisposition to nervous disorders, complains that for the last five or six years he has suffered from a nervous kind of light-headedness, gradually becoming more marked and troublesome. The attacks occur about twice a week, and are brought on by the ideas of space, vastness, height, depth, eternity, or such kindred subjects; and these ideas, however conveyed to the brain, such as the viewing of a large building, or vast area, or in conversation, the description of a voyage, even thoughts of the infinite power of God, or a feeling of loneliness—all and each are able to produce upon him an acute attack which shows itself by pallor of face, a peculiar oppression at the back of the head, palpitation, large drops of perspiration upon the forehead, and a feeling of great dread and exhaustion, and sometimes, as he describes it, a feeling of impending madness. The general condition shows slight tendency to stoutness, with anæmia; the lungs, heart, and kidneys are practically sound. He suffers very much occasionally from bilious attacks, as he calls them, but otherwise is not troubled with headaches, tinnitus, deafness, or any stomach derangement. After an attack he feels sleepy and heavy, and sometimes passes a large quantity of urine; he says he feels nervous, and dreads the onset of another attack. He is occasionally troubled with spermatorrhœa, and reflexes of all kind are very sensitive.

These feelings and attacks may sometimes be avoided or lessened in severity by moral determination; deep concentration of thought will enable him to cross an open space or certain places which otherwise induce these attacks of dread; companionship relieves the feeling of loneliness and fear produced by the thought of taking a holiday in a part of the country new to him. The presence of a cart, even a stick or umbrella in the hand, persons, or trees, gives a sense of confidence when walking an unknown road. Cheerful and lively conversation, with a congenial companion, will always ward off the attacks.

This case is, I think, a typical example of that described in 1870 by Benedikt and in 1872 by Westphal, under the term "agoraphobia," and is, I venture to think, a not uncommon form of nervousness, though exceptional in its extreme forms; it is an essentially neurotic, as distinguished from a hysterical, affection.* It is rarely described in text-books. Quain's *Dictionary of Medicine* gives only a short article, written by Dr. Fred. Roberts, who does not think the complaint idiopathic, but says "it is sequential to some other condition." What that other condition is he does not say. Dr. Maschede is mentioned as describing a case of clithrophobia† in a young man who exhibited giddiness and oppression whenever he entered a small room or narrow space, and was obliged to camp out in the open fields and woods, and only in the depth of winter could he be prevailed upon to sleep in a large and airy apartment with all the windows open. Dr. Maschede also mentions two other similar cases. The author thinks that agoraphobia and clithrophobia ought to be classed under the same head, as in both cases the characteristic symptom is that the patient cannot by any means form an accurate conception of his surroundings.

Dr. Grainger Stewart, in a recent lecture upon "giddiness," thinks that these cases are closely allied to ordinary giddiness produced by what he calls and describes as "contradictariness of sensory impressions." "Normal equilibrium is the resultant of normal customary external impressions, and the symptoms of agoraphobia are produced by the absence or clashing of one or more of these impressions." This explanation seems to me hardly satisfactory, as my patient insists very strongly that there is a distinct difference between the giddiness associated with his bilious attacks and the giddiness which accompanies his agoraphobic attacks; again, companionship can hardly affect a man's appreciation of vertical lines, by which Dr. Stewart thinks the patients guide themselves, and also we find that the mental ideas of infinity, vastness, etc., are just as potent to produce the attacks as are external impressions.

---

*Gulstonian Lectures, by Clifford Allbutt, March 4.

†British Medical Journal, May, 1879.

To me the case seems essentially a form of mental depression in certain faculties, unassociated with delusion and closely allied to what is called simple melancholia. There are disorders of perception, bright light, loud noises, likes and dislikes to persons and things are more pronounced and uncalled for; there is increased irritability to all external impressions, and these are accompanied with some form of deteriorated physical health; but I think the seat of this condition is certainly central, not peripheral. May it not be due to some functional irritation of the cerebral cortical sensory centres, which Ferrier calls the anatomical substrata of ideation?

The prognosis in this case is good, and he has always improved and recovered from his nervousness with the recovery of his usual good general health.

Treatment has been with the object of improving the general health by small doses of cod-liver oil, attention to diet, and the avoidance of such associations as aggravate the disorder. Great relief has been found from wearing a pair of dark-purple spectacles, especially upon bright days. The recumbent position, bathing the head with cold water, or a small dose of some stimulant, will often ward off an attack for some time. The peculiar pain in the back of the head is best relieved by pressure of the hands. A dose of bromide of potassium and strychnia will enable him to mount a hill or do some work which he could not have accomplished and would have shrunk from without it, and he finds he requires a quarter of an hour before the medicine acts. Other medicine he takes from which he is confident he receives benefit—namely, nux vomica, iron, and hydrobromic acid.

The Value of Condensed Milk.

Mr. T. Maben says in the *Druggists' Circular:*

Condensed milk is more digestible than ordinary cow's milk—a fact which is admitted even by those who say it should not be used. It is less liable to turn sour in the bottle, and how great a boon this is, is known only to those who have to do with feeding-bottles. It is less liable to decompose in the stomach. A medical friend informs me that he frequently finds that children fed on cow's milk are troubled with flatulency, diarrhœa, green stools, and want of health generally, and that, on changing the food to condensed milk, these symptoms at once disappear, and a most healthy condition of the body is induced. Condensed milk is less liable to vary in composition, and more likely to be pure. It is well known that the quality of the cow's milk varies with the food supplied to the cow, and in these days it is often the main object to have quantity, quality is frequently at a discount. Besides this, the change of a cow, the introduction of a new cow into the dairy, the use of milk before it is quite free from the colostrum—all these have often been accompanied with dangerous results. Now this cannot happen with condensed milk. It is in the interest of dairymen themselves to use the richest milk for condensing purposes; the cows are fed on nature's food, whether in the green Swiss valleys or the Norwegian *dals*, or "in the pastures of the far-famed Acadia of Longfellow's 'Evangeline,'" as one advertisement sets forth in poetic language; and, if due care is taken to mix and properly condense and preserve the milk, the chances of variation or impurity are indeed few and far between. The conclusion, therefore, to which I arrive is that, when mother's milk is not available, a good sweetened condensed milk is the best substitute; and though it is not by any means a model food, it is not quite so unsatisfactory as some authorities would have us believe.

The Manufacture of Oxygen.

The production of oxygen direct from the air has long been aimed at by chemists. It would appear, from a communication made to *La Nature* by Messrs. Brin frères, that this purpose has been successfully accomplished. They have erected a plant which produces 100 cubic metres per day—a quantity which is far beyond merely laboratory experiments. Their process is based on the property possessed by caustic barytes of absorbing oxygen. A series of retorts is fixed in a furnace, and caustic barytes is inserted in each retort. A force-pump and a suction-pump are connected with each retort, and at a temperature of between 500° to 600° C. air is pumped into the retorts. The air has previously been in a chamber containing lime and caustic soda, to free it from carbonic acid gas. At the temperature named, the barytes absorbs oxygen. At about 800° the resulting peroxide is deoxidized, and, by means of the suction-pump, the oxygen is drawn off. By this process a perfectly pure gas can be obtained in unlimited quantities. The oxidation and deoxidation of the barytes can be repeated indefinitely.

Of course it produces nitrogen as well as oxygen, and the authors believe the manufacture of ammonia by direct combination with hydrogen will be possible.

The applications of oxygen are likely to be very numerous. The authors think it will be found superior to carbonic-acid gas in aërated beverages. For all antiseptic purposes oxygen is of great value, and it is likely to be extensively employed in metallurgical processes, as in its medium elevated temperatures are more readily obtained than in the atmosphere.

Reviews and Book Notices.

BOOK NOTICES.

Lecons de Clinique Chirurgicale. Par le Dr. Charles Monod. 8vo., pp. 127. A Delahaye, Paris, 1884.

In a series of half a dozen clinical lectures, Dr. Monod treats of cancer and tuberculosis of the testicle, of cancer of the breast and pleural fistula, of hare-lip and perforating diseases of the foot. His teaching is clinical, amply illustrated by cases, and delivered in that pointed, incisive manner for which the French have such aptitude. Any one who is in search of further information on the topics we have named will do well to order this book.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address
DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE COLLECTIVE INVESTIGATION OF DISEASE.

The plan of uniting a large number of persons at one time in the investigation of disease is becoming more popular as its results are better known. Having definite questions to answer, the attention of observers is fixed on those points which are more obscure. There are difficulties in the way of estimating the results of these observations, more serious than those obtained in hospitals, for obvious reasons; but on the other hand, they are in certain respects more valuable than hospital statistics. These latter deal principally with the broken-down population of large cities, while the "collective investigation" plan deals with the actual patients of the practitioners.

The Pennsylvania State Medical Society appointed a committee to prepare cards and forms for such investigation, and the committee has recently sent such cards to members of the society. They are upon acute pneumonia, chorea, and acute rheumatism, each one of which it is requested that the member will fill up from a case in his own experience. The questions are for the most part arranged so that they can be answered by simple erasures, thus involving the minimum amount of time and trouble on the part of the observer. The cards thus filled must be returned not later than the first day of April, 1885, when the committee will begin to prepare the reports which it intends to make to the society at its annual meeting in May, 1885; but it is of course desirable that the cards should be returned as soon as the observations are completed, as the making of the reports involves much labor.

In preparing the cards, the committee has intentionally adopted precisely the same form and color for each disease, as the Collective Investigation Committee of the British Medical Association, because it is evident that if any advantage is to accrue from an international investigation, it must largely depend upon a uniformity of method. It would have been easy to modify the English cards and thus give an appearance of greater originality; but as there was no especial merit in such course, and the advantages of uniformity

were secured by leaving them unchanged,' this was done.

The chairman of the committee is Dr. James Tyson, 1506 Spruce street, Philadelphia, who is prepared to furnish the forms to those who will take an interest in filling them up.

We recommend to our readers in this State to send in such reports, and those in other States may think it worth while to obtain specimens of the forms used so that they may be extended as widely as possible. In this way the maximum benefit from such a scheme will be obtained.

THE LUNACY LAWS.

The Rhinelander lunacy case has attracted considerable attention in New York, and is of some interest as showing the new mode of procedure in the trial of criminal cases in that State, when there is an allegation of insanity.

The old mode of trying the issue at the same time that the guilt of the prisoner is determined, is not a satisfactory or practical way of securing justice, and it is now done away with. The rule now is, to settle the question of insanity before the prisoner is called upon to plead, and at a time when it will not be complicated by other issues. In the Rhinelander case the plan worked well, and the result is mainly of interest as throwing some discredit upon expert evidence.

Recorder Smyth, of the Court of General Sessions, before whom Rhinelander was brought, appointed a commission to take testimony on the question of insanity and report. This commission prosecuted its duties for several weeks during the summer, and amassed an immense amount of evidence from experts and non-experts, with the result that the majority of the commission reported that Rhinelander was insane. A minority report was also presented to the opposite effect. These two reports were carefully considered by the Recorder, and in an elaborate opinion recently rendered, he adopted that of the minority. He caustically said that the expert evidence was practically of no value. That the physicians were directly opposed to one another on the question of insanity, and that those who testified in favor of insanity were totally opposed to each other as to the grade of nervous disease suffered by the prisoner. There has not been so cutting a commentary on the existing system of expert evidence in a long time, and it is not unlikely that public opinion will ere long require some change, such as that of calling the experts at the instance of the court itself, and not as witnesses for a particular side. Until something like this is done a physician can never be entirely free from bias.

PAY OF NURSES IN HOSPITALS.

The question of compensation for nurses and those employed in hospitals in caring for the sick, is a matter of some importance, and the courts are frequently called upon to determine the responsibility for such compensation.

In a recent case in Michigan it appeared that the charter of a city required the common council to take proper measures for the preservation of the public health, and at the same time a statute declares that patients of pecuniary responsibility shall pay for the services rendered them by the hospital nurses.

The suit in this case was brought against the city authorities by the nurse, and the court held that the suit was a proper one, notwithstanding the statute making the individual liable, and ordered judgment.

The opinion of the court is in part as follows: "The duty to guard the public health and prevent the spread of contagion was imperative, and the power of the common council was commensurate with the duty. Neither the power nor the obligation could be lessened by the failure to designate a sub-agency. * * * In providing that what is done shall be at the charge of individuals, it is not intended to exempt the public from immediate liability. It would be impossible under such a regulation to effectuate the general object.

"Individuals would not be willing to provide necessaries, and serve as nurses and assistants at the instance of the public, if compelled to collect their pay of the patients or their relatives.

"The public is first and immediately responsi-

ble, and the intent of the statute is to enable the public to obtain reimbursement from those who ought to sustain the expense."

Notes and Comments.

Huchard on Antipyrin.

Dr. Huchard terminates a lecture on the therapeutics of the new antipyretic antipyrin, which he delivered at the Hôpital Bichat (*Union Médicale*, November 29 and December 6), with these conclusions:

1. Antipyrin constitutes a powerful and certain means of lowering the temperature in almost all febrile diseases, as typhoid fever, pulmonary phthisis, pneumonia, pleurisy, acute articular rheumatism and cerebral rheumatism, angio-cholitis, erysipelas, diphtheria, puerperal fever, scarlatina, phlegmon, abscess, etc. It mitigates the symptoms which are due to the pyrexia, acceleration of the pulse and respiration, dryness of the mouth, etc., but it does not seem to possess any *direct* action on the respiration and circulation.

2. It is an antipyretic but not an antiperiodic, whence its inefficacy in intermittent fevers as a *preventive* of the paroxysms.

3. Its administration only gives rise to slight and occasional complications, such as moderate sweating, pharyngeal constriction, slight nausea or vomiting, and in some relatively rare cases to a rubeoliform or scarlatinaform eruption. No tendency to collapse is produced, nor any intoxication such as is caused by preparations of cinchona and salicylic acid.

4. Numerous observations have demonstrated that it constitutes a powerful, and up to the present time the sole means of efficaciously lowering the temperature in tuberculous subjects. After a dose of two grammes, administered especially in the evening at the time of the recurrence of fever, the temperature falls half a degree Centigrade, by the end of half an hour, and sometimes after a quarter of an hour. It then diminishes progressively, until the normal temperature is attained in an hour and a half or two hours. It is, however, sometimes necessary to prescribe an hour or two later another dose of one or two grammes; but in phthisical subjects, it, in consequence of the very certainty of its actions, and with the aim of avoiding accidents that may be induced by hypothermia should only be administered in small and increasing doses, as from two to four grains.

5. The antithermic effect is ordinarily maintained in these patients for from six to nine hours, and is sometimes perceptible on the following day, during which the temperature does not regain its previous height. The subsequent rise of temperature takes place progressively, resembling in that the course of defervescence. It is never sudden, as with kairin, and is never accompanied, like the latter substance, with more or less prolonged shivering.

6. It is eliminated in the urine, in which its presence is recognized two to four hours after its administration, during a period of from 30 to 48 hours. Some drops of perchloride of iron poured into urine of patients taking this medicine immediately produces a highly characteristic red color.

7. Dr. Huchard cannot speak from his own experience as to its effects in typhoid fever; but he is disposed to regard the doses of from six to eight grammes per diem, recommended by various observers, as excessive, as in several of the cases in which they had been employed a condition of hypothermia has been induced, the temperature falling to 35° or 36° C. In typhoid fever, also, the temperature, after having been lowered, will about the fifth or sixth day rise again a degree Centigrade for about an hour, after which time it resumes its regularly descending progress. Dr. Huchard has also noted the same temporary ascent of the temperature during the apyrexia, due to action of antipyrin on the fever of phthisis.

Koumiss.

Before the Medical Society of London, November 17, 1884, Dr. Carrick read a paper on the preparation of koumiss from mares' milk. He observed that the milk of mares resembled that of women more than that of any other animal. The milk of women, mares, and asses was alkaline; the milk of cows was neutral, or more commonly acid. In the former class, the casein was precipitated in thin flakes; while in cows' milk the clot was firmer and more solid. Women's and mares' milk could not be churned into butter, owing to the small percentage of fat present. The koumiss of the Steppes was, in fact, mares' milk which had undergone the lactic and and alcoholic fermentation. The amount of alcohol and of acid depended on the length of time for which the fermentations were allowed to proceed. Koumiss, being remarkably digestible, was of great use in wasting diseases; it could be consumed in large quantities for considerable periods. It was especially useful in phthisis, where it improved digestion and nutrition: and its action on the

mucous membrane, as well as its slightly constipating action, were of great use in ulceration of the intestine. It was contraindicated in diseases producing overloading of the right side of the heart, in atheroma, or aneurism. The beneficial effects of koumiss were best seen in patients who visited the Steppes, and it might be advisable to repeat the visit for six or seven summers in succession.

Dr. Jagielski had introduced koumiss into this country fifteen years ago. Clinical experience led him to believe that koumiss made from cows' milk was as good as that made from mares' milk. It was necessary to remove part of the casein and part of the fat, and to regulate the amount of sugar.

Dr. Theodore Williams, while recognizing that the koumiss made from mares' milk was the original preparation, had found cows' koumiss very useful in severe vomiting or hysteria, but not in phthisis.

Dr. Cullimore suggested that, in the "koumiss-cure," much importance ought to be attached to the pure air of the Steppes.

Dr. Edmunds thought that it was necessary to ascertain the relative nutritive value of koumiss, as compared with other dietaries.

Dr. Carrick thought the air of the Steppes, and the violent exercise taken by the patients, were of great importance in the "cure," as applied to phthisis. The experience at St. Petersburg confirmed the view expressed by Dr. Williams, that koumiss, without the other attendant conditions found in the Steppes, was of little use in phthisis.

Strangulated Hernia in an Infant Three Weeks Old.

Since such cases are very rare, the following case, which Dr. A. Haslewood reports in the *Lancet*, December 28, 1884, is worthy of note:

"On September 22, 1884, I visited a child three weeks old, for whom I had prescribed for symptoms of what the father described as 'spasms.' The child had been in great pain all night, and had been vomiting frequently; the abdomen was immensely distended with flatulence, and the child was evidently very ill; the skin of the face was pinched and shrunken. Over the right external inguinal ring, and into the scrotum, was a very evident hernial swelling, which, the parents said, was not present the previous day. Chloroform was given, and taxis fairly tried, with no effect upon the hernia. I therefore arranged to operate as soon as possible, which I accordingly did the same evening, when, after thorough insensibility was produced, taxis was again tried, both by myself and my friend, Mr. Arthur Shipton, whose valuable coöperation I had throughout; but we failed to produce reduction. On cutting down upon the tumor, a very tightly strangulated direct inguinal hernia was brought into view. Reduction was impossible without opening the sac. The constricted portion of bowel was very dark plum-colored, and formed a loop of about four inches in length. The division of the stricture was by no means easy, owing to the minute size of the tissues rendering it impossible to make good use of the finger in finding the stricture. However, with time and great care a director was passed under the constricting edge, and the stricture divided. Even then the reduction was not at all easy, and the appearance of the bowel so tightly bent round on itself renders it easy to imagine that reduction without operation was out of the question. The further progress of the case was very gratifying. The sickness ceased, the bowels acted naturally the following day, and the child to-day (November 11) is looking extremely well. I would strongly advise any surgeon having a case of a similar nature to select daylight for operating.

The Treatment of Phthisis.

What little we know about this matter is very well summed up by Dr. J. Burney Yeo, in the *London Med. Times*, December 6, 1884:

1. In the first place, to prevent or amend those faults of constitution, organization, and development which predispose to the acquirement of this disease.

2. To prevent or cure those local pulmonary affections which may induce a tendency to this disease, even where no constitutional predisposition is found to exist.

3. To prevent the possible spread of the disease by the conveyance of its germs from the sick to those who are necessarily brought into close contact with them.

4. To endeavor, so far as possible, to antagonize the influence of the infective organism *in situ*, and in its action on the constitution. To attempt to hinder the progress of its development and reproduction, and its extension to the sound parts of the affected lung, and also to the sound unaffected lung, and to prevent the infection of other organs. This is what is understood by antiseptic treatment.

5. To lessen and remove the *fever* and other constitutional disturbances dependent on the in-

fection of the constitution, as well as on the local inflammation.

6. To lessen and arrest the local irritation and inflammatory and catarrhal changes when evidences of such make their appearance.

7. To improve the disturbed and defective nutrition by all the means in their power, medicinal, regimenal, climatic, etc.

8. To relieve the various distressing symptoms that occur during the course of the malady.

9. To diminish as far as possible the evil consequences of the several grave complications incident to its course.

Psoriasis—Verruca—Epithelioma, a Sequence.

Dr James C. White, of Boston, in the January number of the *American Journal of the Medical Sciences*, presents brief notes of two remarkable cases of disease—cases extraordinary, not for the rarity of the pathological processes they represent, but for the very unusual sequence of tissue-change exhibited in their course. There were three distinct pathological affections of the cutaneous tissues: psoriasis, verrucous hypertrophy, and epitheliomatous new growth; not occurring independently of each other, but as successive, mutual transformations in the above order.

The three dermatoses which enter into the clinical history of Dr. White's case, and which are in their nature apparently as unlike as their companionship is rare, have a close affiliation in their anatomical relations. The transformation of patches of psoriasis into horny or warty, permanent growths is not referred to in most works on dermatology as of possible occurrence even; the transformation of verrucous growths into epithelioma is of not very infrequent occurrence; but the uninterrupted sequence followed in this case, psoriasis — verruca — epithelioma, or in other words psoriasis, as a cause of carcinoma, is extremely rare or unparalleled in dermatological history. The practical lesson to be deduced is that the transformation of patches of psoriasis into verrucous hypertrophy must be regarded as an ominous occurrence, and that the softening or other change of such horny growths demands thorough excision without delay.

Cardiac Debility.

From the *Medical Record's* report of the fifty-seventh meeting of German Naturalists and Physicians, we learn that Professor Seeligmüller, of Halle, presented a communication upon this subject. The author pictured the group of symptoms, usually called cardiac neurasthenia, as follows: after a period of cardiac disturbance, palpitation, pain in the precordial region, there ensues a condition of general weakness, expressed by fatigue after slight exertion, insomnia, forgetfulness, and distraction, and a depression of spirits. At the same time, despite a good appetite, sometimes even boulimia, there is a falling-away in nutrition, the extremities are cold, and there is at times a feeling of formication. In the absence of any organic changes, the author was inclined to refer these symptoms to anomalies of innervation, especially as they occurred most frequently after psychical disturbances, as prolonged sexual excitement, severe mental labor, combined with broken rest, etc. Rest, warm baths, good nourishing food, sea or mountain air, and quinine in small doses often exerted a favorable effect.

Dr. Wagner spoke of the difficulty of diagnosis at the first examination in these cases. In all heart affections where there were no apparent physical disturbances, especially in those of advanced years, disease of the coronary arteries should be suspected. The speaker had seen cases similar to those described by the author of the paper in women who had borne many children or who suffered from certain forms of uterine disease. This condition was caused in those cases by an overloading of the abdominal organs with blood, and was much benefited by wearing an abdominal supporter.

The Administration of Nitrous Oxide.

In the course of an address on anæsthetics by Dr. Woodhouse Braine, in the *Brit. Med. Jour.*, November 29, 1884, we note the following:

Pregnant women, even as far advanced as eight months, take nitrous oxide well. I may here mention the case of two patients, who were suckling, and in whom the shock from the extraction of a tooth, without the gas, stopped the secretion of milk; subsequently, having to undergo a similar operation, under like circumstances, they determined to take the gas, and in neither instance did any derangement of the function of lactation occur. Children with chorea, and people who have had hemiplegia, take the gas well. In phthisical patients, if the mischief is extensive, some caution is necessary; as in these cases the anæsthesia deepens after the removal of the face-piece, so that it is neither necessary nor advisable to start with any deep amount of insensibility. It is perfectly safe to administer this agent to epileptic patients. I have met with several cases where the extraction of a tooth, without gas, has pro-

duced an epileptic attack, but I have never seen one occur when gas has been given.

A little time ago I accompanied a surgeon to a case of circumcision, on a boy, about 2½ years old. On entering the room I found the patient lying on the floor, in a very severe epileptic fit. In a short time he became partially awake; and, not seeing any good reason for waiting, I anæsthetized him there and then; and, after the operation, he recovered in the usual way.

Great age is no bar to the administration of nitrous oxide; my oldest patient, a lady, having reached the age of 94.

Intra-Uterine Applications of Nitric Acid.

According to Dr. Thomas More Madden (*Brit. Med. Jour.*, November 29, 1884), the most active of all the agents employed in intra-uterine medication is fuming nitric acid, introduced into modern gynæcological practice by Dr. Kidd in the Coombe Hospital, and subsequently employed by Dr. Atthill in the Rotunda, and by himself in the Mater Misericordiæ Hospital, Dublin, long before it was thus applied elsewhere. In the intra-uterine use of nitric acid, it is necessary that the os uteri should be fully dilated and exposed to view, the posterior vaginal wall properly protected by the duck bill speculum, and the uterus well drawn down by a uterine tenaculum, designed for this purpose, and which can be easily disengaged from the firm hold on the cervix, and withdrawn by merely turning the screw-adjustment in the handle. In this way, the uterus may be well swabbed out with the fuming acid, the whole charge of which is thus expended on the intra-uterine surface, so as to avoid injuring the vaginal walls or external parts; though as an additional precaution, these should, moreover, be smeared over with vaseline beforehand. Immediately after the application, the uterus and vagina should be thoroughly washed out, until no trace of acid is discoverable in the returning water; finally, if any pain be complained of, a morphia-suppository should be introduced. When thus employed, nitric acid may generally be as safely as effectively used in those cases of intra-uterine disease in which its application is really necessary, and to which it should be carefully restricted.

The Early History of Galvanism.

Dr. C. A. Gordon thus concludes a paper on this subject in the *Med. Press*, November 19, 1884:

1. A knowledge of electric phenomena had existed, although in a very incomplete stage, from very ancient times.

2. Throughout the sixteenth and seventeenth centuries investigations on that subject were pursued, and many successive discoveries effected.

3. Electricity was practically utilized in 1748; "galvanic" phenomena observed in 1762; that is, considerably before the date of Galvani's experiments.

4. The chief experiments recorded of Galvani were performed on decapitated and dismembered frogs; others upon amputated limbs and executed criminals. Thus the non-necessity of *living* animals for the purposes in view is indicated.

5. So long as experiments were restricted to persons and animals, whether alive or dead, no definite advance took place in the useful application of the power. It was only when experiments came to be performed upon salts and metals that real progress began.

6. In 1721 "the germ of the electric telegraph" was discovered; in 1753 a telegraph was in actual operation—both these dates anterior to the time when Galvani's experiments were performed.

7. To Volta is due the credit of having contrived in the form of his "pile" the first "galvanic" battery so-called.

Irritable Hymen.

Dr. Angus Macdonald reports the following case in the *Edinburgh Med. Jour.*, December, 1884:

Mrs. G., æt. 26; one year married, no children, but one miscarriage. Admitted to ward 28, complaining of dyspareunia.

Physical Examination.—In the deeper part of the vulva, immediately outside the hymen, and involving it, there are large red, excessively irritable patches, which give rise to extreme pain when touched, and render marital intercourse impossible.

Treatment.—The part was dressed with iodoform for some time; but as this treatment was only partially successful, Dr. Macdonald, on January 22, 1884, removed the mucous membrane all round the hymen, and brought the edges together with a continuous catgut suture.

February 18.—All special irritability has departed from the irritable surfaces, and the patient was dismissed cured.

The above is one of a class that gives considerable trouble to the gynæcologist. I acted upon the suggestion of the late Dr. Marion Sims, and removed the irritable hymen and adjacent tissues with the knife. To get rid of capillary oozing, I brought the surfaces together with continuous

catgut suture. The patient did well, and went out apparently cured. Whether the cure has been permanent I have not been able as yet to ascertain.

One Thousand Cases of Abdominal Section.

Having performed a series of one thousand operations of abdominal section, Mr. Lawson Tait sums up his results in the *Medical Record*, January 3, 1885. He premises, in order that his remarks may be the better understood, that in every case the peritoneum was involved.

ANALYSIS.

	Cases.	Deaths.	Percentage Mortality.	
Exploratory incisions	94	2	2.1	
Cystoma: Parovarian	65	2	3.07	8.1
Cystoma: One ovary	239	26	11	8.1
Cystoma: Both ovaries	101	5	5	8.1
Removal of appendages for myoma	99	7	7	
Removal of appendages for inflammatory disease	201	10	5	
Removal of appendages for epilepsy	6	0	0	
Removal of appendages for deformity	1	0	0	
Hysterectomy	54	19	35.7	
Opening for draining pelvic abscesses	30	0	0	
" " incomplete operations	30	15	50	
" " cholecystotomy	13	0	0	
" " nephrectomy	3	0	0	
" " nephrotomy	9	0	0	
Extra-uterine pregnancy	11	2	18	
Hepatotomy for abscess and hydatids	10	0	0	
Hepatotomy for hydatids of peritoneum	2	0	0	
Tumors of omentum and mesentery	5	0	0	
Enterotomy	8	1	12.5	
Adhesion of intestines relieved	2	0	0	
Chronic peritonitis opened and drained	7	1	14.3	
Acute peritonitis	2	1	50	
Umbilical hernia	4	0	0	
Cæsarean section	1	1	100	
Scirrhus tumor of abdominal wall	1	0	0	
Suprapubic lithotomy	1	0	0	
Enucleation of myoma	1	1	100	
	1000	93		

Mr. Tait details his experience with various anæsthetics, and comes to the conclusion that he is now better pleased with a mixture of ten parts of ether and one part of chloroform, given by means of Clover's apparatus than with any other. This mixture is rapid in its action, and not at all unpleasant to the patient, and the sickness after it is far less than with anything else he has ever used. It does not produce bronchitis, nor does it arrest the secretion of urine as ether does.

A Simple Treatment for Strangulated Hernia.

The *Med. Record*, January 3, tells us that a correspondent who has forgotten to attach his name to his article writes calling attention to a simple expedient that he has resorted to successfully in cases of strangulated inguinal hernia after taxis had failed. It consists in dilatation of the constriction which produces the strangulation at the internal abdominal ring by passing the finger along the inguinal canal, carrying the integument before it until the constricting ring is felt, which generally is easily done; the finger is then gently insinuated into the opening, and if the band of opposing fibres does not yield readily, gentle pressure is made against the upper border of the ring until it is felt to give way, when a resort to taxis again will ordinarily result successfully.

The advantages to be gained by this expedient are that it can be tried as soon as moderate efforts at taxis prove ineffectual, and before the tissues involved are injured by prolonged or severe manipulation; the patient is saved from the dangers resulting from delay; and the dangers attending operative interference, with the complications and sequences which may arise therefrom, are supplanted by a procedure which is harmless in itself and is not liable to be followed by any complications.

He finds that there is no danger of creating a larger permanent opening at the internal ring. He has tried it in five cases.

Painful Mamma in Young Girls.

While not very common, yet we occasionally read of this condition, and it is well that we should know that before the Harveian Society of London (October 16, 1884), Mr. John H. Morgan described the case of a well-made girl, aged 11½ years, who had suffered from severe pain in the left mamma for some time, which had become more acute lately; the gland was very little enlarged, and showed no symptoms of inflammation, but was the seat of great pain, and was very tender to the touch. The pain was continuous, with exacerbations. There was no history of injury; the catamenia had not appeared. Shortly afterwards, the right mamma became affected in an exactly identical manner. Neither local nor general treatment afforded relief. After some weeks, the pain began to intermit, and at length gradually disappeared. Notes were read of six other similar cases, in five of which the left, and in one the right, mamma was the seat of pain. The children were between 10½ and 12 years old; none had menstruated, and in none was treatment, either local or constitutional, of much benefit. It was suggested that this pain was not due to inflammation, but to some developmental changes in the gland, in sympathy with changes in the ovaries and in the organs of generation.

Cocaine in Laryngology.

Dr. Edmund Jelinek contributes some interesting statements on this subject to the *Wiener Med. Blatt.* As the result of numerous experiments in Schrötter's clinic, he says that, if the hydrochlorate of cocaine, either in powder or in the form of a strong solution, is applied to the mucous membrane, a marked diminution of the sensibility of the parts is noticed within a minute and a half. A solution of one part in ten or twenty is recommended, the formula suggested being as follows:

Hydrochlorate of cocaine,	1 part.
Alcohol,	2 parts.
Distilled water,	3 parts.

In examinations of the nose and larynx, it is sufficient to pencil the anterior and posterior surfaces of the soft palate, the posterior wall of the pharynx, and the base of the tongue, the process being repeated after the lapse of a minute, if necessary. The local anæsthesia continues for about ten minutes. Prof. Schrötter speaks in the highest terms of the new remedy. He has produced most gratifying results by its use in cases of acute and tuberculous laryngitis attended with extreme irritation. Both Schrötter and Störk have removed papillomata from the vocal bands after inducing local anæsthesia, and testify to the value of the method.

Tuberculosis of the Uterus.

In the *Med. News*, January 3, 1885, Dr. W. J. Jones, of Baltimore, calls attention to this condition, which, though comparatively rare, yet has not received that attention from gynecological authors to which it is entitled. The clinical diagnosis can be based upon a persistent leucorrhœal discharge and other symptoms which would point to uterine troubles; and in any patient of a tuberculous tendency, in which these symptoms are present, we should be led strongly to suspect an involvement of the genital organs. The diagnosis is often aided by the expulsion of caseous masses from the uterus. Dr. J. evidently agrees with Koch, for he considers the discovery of the bacilli in the secretions a sure means of diagnosis.

In the event of such a case found during life, before the secondary involvement of the surrounding tissues has taken place, a knowledge of how to treat it will present itself for consideration. The authorities which he has examined upon that part of the subject have little or nothing to say. Good hygienic surroundings, tonics, and good food, and perhaps the use of iodoform topically, might at least keep the disease at bay, and thus prolong the patient's life.

Erysipelas as a Complication of Pregnancy and Labor.

In the *American Journal of the Medical Sciences* for January, Dr. G. H. Balleray records two cases of labor with concurrent erysipelas without untoward result. He points out that the management of labor in the case of a woman suffering from erysipelas does not materially differ, other things being equal, from the management of a case of normal labor. The accoucheur should abstain from frequent vaginal examinations during labor; and such examinations as are necessary should be made with *clean* hands. The placenta should, if possible, be delivered by Credé's method; thus avoiding the introduction of the finger or hand within the genital canal. A full dose of ergot should be given after the delivery of the placenta; and the uterus should be gently manipulated until it is *firmly* contracted. In the after-treatment, the nurse should be forbidden to touch the genitals of the patient, without having previously washed her hands thoroughly with *hot* water and soap. The use of antiseptic vaginal injections should be commenced within twelve hours after delivery, and continued as long as there is any indication for their employment.

Laisar's Treatment of Scabies.

The Berlin correspondent of the *Jour. Am. Med. Ass.* (December 13, 1884), tells us that Dr. Laisar's treatment of scabies is as follows:

He has several private bath-rooms, conveniently arranged for all kinds of treatment. A tub of water is charged with a small amount of corrosive sublimate. The patient is stripped, rests quietly in the bath for ten minutes, being careful to keep all parts of the body covered with water. The nurse then washes him all over with green soap, washes it off, then goes through the same process again. Then the entire body is covered by a paint-brush with a preparation of the oil of cade in alcohol. This is washed off as far as possible with green soap, when the patient gets out of the bath and is thoroughly dried. Then the entire body is covered with an ointment of naphthol, sulphur, green soap, and simple ointment, and the patient is told to dress, and to wear the same underclothes until termination of treatment. The latter application is extremely painful, and its effects must be carefully watched.

Enemata of Ipecacuanha in Sunstroke.

From an exchange we learn that Dr. Jos. Baucroft (*Australian Medical Gazette*), finding it difficult to administer medicines by the mouth in

cases of sunstroke, as they may be drawn into the windpipe, and observing that cases which vomited made better recoveries than others, tried emetics, and found it easy to bring about vomiting by injecting ipecacuanha into the rectum. This he does by as soon as possible injecting into the bowels a drachm of ipecacuanha rubbed up in two ounces of water. After the injection, he removes the whole of the dress from the chest and abdomen and irrigates the surface with iced water in a watering-can so long as the temperature seems to require it; but, though the skin may be cooled, the thermometer will frequently indicate a body-heat of from 105° to 108°. Vomiting generally takes place within half an hour, and it is astonishing what a quantity of fluid is at times rejected.

Mediate Syphilitic Infection in Glass-Blowers.

Before the Liverpool Medical Institution (Nov. 20, 1884), Dr. Bernard related four cases. The cases all presented themselves for treatment within the space of three months, the first in August of the present year, and they all worked under one roof. In every case the lips were the seats of sores, and the sub-maxillary glands were enlarged, whilst the penis was free from disease, and the inguinal glands were unaffected. The speaker then referred to Lancereaux's mention of the subject, and suggested that each workman should have and use his own blow-pipe, as was the case in France, that the possibility of such accidents might be avoided.

Correspondence.

Heart Failure.

Eds. Med. and Surg. Reporter:—

I have been particularly interested in the description of symptoms, if not a disease, portrayed by the pen of Dr. Roberts Bartholow. I refer to "Nervous Prostration." While it may possibly be the results of a reflex action, the direct effects are often only seen, and are the symptoms demanding prompt attention. I allude to one of the main and most prominent symptoms, *heart failure*, and look upon this distressing symptom as almost a disease of itself. The "heart failure," which is an almost if not a constant symptom, is the one we are called on to treat.

Having lived in a miasmatic district for twenty-six years, have seen more of this trouble in an isolated form than most any one. Frequently, with the slightest chill, in fact only a nervous rigor, with no appreciable rise in temperature, the entire nervous system is depressed, and the heart is brought almost to a standstill. Like a drowning man gasping for breath, the heart tumultuous, flutters, beats, stops, intermits, and starts with an acceleration due, certainly, to some nervous excitement brought to bear at a head centre. Whether this is malaria, dyspepsia, gout, rheumatic poison, or tendency to a carditis, is the question. One day the patient can digest, as he says, a "peck of wool and a hamper of gums;" the next day he cannot digest cold water—one day he can eat with impunity anything, the next day he dare not touch the simplest food. Angina comes on, and a thousand and one other troubles that make life and living a constant terror. I think it is unfortunate to couple these distressing symptoms with hypochondria and hysteria, when the heart and circulation, not at the will or mercy of such beings, as a general rule tells its own tale.

These symptoms often come on, not in the hours of waking—but persons often are wakened by a tumultuous effort or intermittency of the heart, to find themselves with rigors, perhaps no chill, and not cold even, and the heart depressed and sinking under some terrible influence This is often cut short by mustard plasters below the nipple on the left side and over the epigastrium; the left breast is often left sore, the muscles frequently jerk like tetanic spasms, and a soreness extends along the tract of the nerve, distributed to breast and shoulder, showing plainly some nerve excitement. It is then the digestion fails, or is altogether perverted—is this a cause or a sequence? The digestion was fine only the day before; they could eat cabbage, onions, and all kinds of vegetables with impunity; but to-day this little nerve influence has exhausted nearly the vital powers. Malaria may excite this state of affairs, perhaps, but it comes hot or cold, melting or freezing alike. I could enumerate a thousand and one symptoms, even while every organ is performing its function—the liver acting, the kidneys in fair coudition, without any apparent influence, while sleeping quietly, these spells have come on.

Having suffered all the above at times, and having been declared sound in body and mind, having little to vex or harass me, and not being easily vexed or harassed at small things, I can speak from a sad experience of suffering, with little aid from medicine.

I reported a case some time ago in the *Medical World*, a so-called typhoid fever case, where many of the nervous symptoms of typhoid fever were present; it was, however during an epidemic similar to the Kentucky and Virginia plague, which, with malarial complication, answered a better description of pernicious fever. The temperature fell regularly twice a day; the transition was sudden, in one-half to one hour, without medicatton, causing stagnation of blood, a venous congestion of lungs and kidneys, with a catarrh of both as a complication, and a marked failure of the heart, and sinking of all the vital powers, requiring brandy, milk, and quinine in *small doses*. Any change in temperature could only be detected by the thermometer in mouth and rectum. Pulse became weak, scarcely perceptible, and often too frequent to count; again slow and intermittent, producing the most alarming results, requiring constant attention. Now the only rational explanation of these sudden changes and their influence on the digestion, if it be reflex, it must be

some poison or irritation to nerves distributed to internal organs—stomach, lungs, heart, bowels, or kidneys—these influences transmitted to the base of the brain, in turn are again sent to stomach probably first, instead of exciting the gastric juice with its acids to aid digestion. Oxalic acid is developed in such quantity as to prevent digestion and irritate the stomach, again causing darting pains or even jerking of muscles. Sometimes a diaphragm, a sense of tightness across the breast, and a sensation as though the stomach and chest were inflated beyond bearing, beside a constant disposition to pass gas by bowels, and often eructations and an acid disagreeable liquid. These symptoms are only while these paroxysms are on them, and not constant. Often the perspiration smells acid and garlicky, and urine shows oxalic and uric acid crystals. Urine generally pale, amber color and low specific gravity, often as low as 1007. There is seldom any disposition to vomit, but when an effort is made to do so the matter emitted is generally very acid, showing evidently the presence of more acidity than required for digestion. Acids taken into stomach generally produce the cramp or increase the trouble, often exciting muscular spasm or tetanic contractions of muscles of breast. Alkalies increase the tightness by generation of gases, and often little eructations from them.

Now, are the dyspeptic symptoms the cause or the result of the "nervous depression," or are not heart failure and want of blood in stomach causes of perverted digestion? Yesterday digestion was good, could eat anything; last night a spell; today pains over kidneys, depressed, and stomach oppressed when anything is taken into it; shooting pains through the breast and membranes of left arm at shoulder and elbow; sciatic pains only after such spells or paroxysms.

I am satisfied that we can find in an oxalic acid diathesis a probable if not pertinent or just cause for erratic rheumatism, and to it I think must be ascribed much of the cause of nerve prostration and heart failure, for I hardly think that uric acid, except in larger quantities than are usually seen in such cases, would produce such results, or even urea; beside, urea in sufficient quantity to interfere so with digestion, etc., would evidently produce unpleasant effects on the brain. which is almost always free, except as far as the terror or constant forebodings of the result of this oppression. Besides, I think the oxalic acid excess may account for the headaches or neuralgias often felt, and the diaphragm or feeling of having swallowed wind, as well as tightness across the breast, and constant and distressing symptoms—the shooting pains or even the jerkings or muscular twitchings so often felt, as well as the pains, soreness, or deadened feelings at the base of the brain—no doubt when all these exciting causes center to discharge their venom through the nerve-centres to distant organs. Another name for these conceptions in my own case. Chlorate of potash and bismuth subnit. have bad effects, frequently irritating the urethra and prostate gland. Muriate of ammonia taken internally, ammonia is disengaged, showing other acid than muriatic present. Would uric acid produce such an action? Ammonia increases bad feelings. Nitric and nitro-muriatic acid will produce angina, and iodide of potash will produce constriction of throat and jaws, like jock-jaw, or when a person gapes and his jaws catch and lock, he can neither open or shut his mouth hardly, until the contractions of muscles are over. Soda bicarb. disagrees, with oppressive fullness felt in breast, or tightness. Muriated tincture of iron disagrees also, producing same unpleasantness and fullness in head, even in five-drop doses three times a day. I can take bromide of potash, but not bromide of soda. Bitters and quinine seem to occasion a dysphagia or constriction about throat like wind had been taken into the stomach, or belladonna had been swallowed. I never have any thirst, care little for water or liquids, except at meals, and only then while taking solid food. Sometimes have a burning sensation after these paroxysms through heart.

I have given you my own symptoms, as exemplary of those generally complained of by others. You may have noticed my last article, "American Pork," in *Medical World*. We had what the Kentucky and Virginia mountaineers have had with the drouth. We also had measly hog cholera pork, and doubtless can trace our epidemic in part, if not in whole, to it. "American Pork" contains more beside trichina. *I can assure you* cholera hogs are continually sent out; diseased meat, and meat saturated with saltpetre, equally destructive to intestinal mucous membrane and kidneys, in the manner in which it is used—sliced and fried without boiling or soaking. I can give you some dots here.

CHAS. C. THORNTON.

Thornton, Miss.

The Profession in Pennsylvania.

EDS. MED. AND SURG. REPORTER:—

The Legislature of the State of Pennsylvania in times past have been turning professional somersaults, and exhibited very exalted ideas of the wants of the medical profession. For "instance:" On the 24th of March, 1877, a law was passed "that no person should practice medicine or surgery without a diploma or five years' practice."

There lived near me a young man who had just started out to practice homœopathy without any medical education whatever, and the passage of that law scared him so badly that he hired a practicing homœopathic physician to attend a course of medical lectures in his name, he paying the expense. He knew that he could never get a diploma on his own merit; but he is as good an M. D. as any one now.

That is the only wonder that law ever worked here to my knowledge.

Same act, sec. 4, relates to transient practitioners, but is a dead letter. One of those traveling station mountebanks stops at the town of ——, advertises liberally that he has *permanently* located, and until a suitable office can be secured, will be at Hotel ——, rooms ——; but in a week or ten days, having lined his pockets with shekels, goes to the next town to play the same game.

Registry Law, approved June 8, 1881, provides for the registration of *all* practitioners of medicine and surgery.

But a few miles from my place lives a man per-

fectly illiterate—he cannot read a word in any language, cannot write his own name—but he is a registered practitioner, and exhibits the receipt he got from the Prothonotary for his fee to those ignorant as himself, as his diploma. Says he got it from the State of Pennsylvania; didn't go to *Phydelphy*, where they keep them to sell, and buy it, as most of them do.

I fail to see how that law amounts to anything. You can go to the "books" and see who have diplomas and who not, but that does not regulate the practice of medicine, nor raise the standard of medical education. Battle with this problem as long as you may, legislate till the ballot-box is worn out, but just as long as those illiterate charlatans are permitted to blow their horns over the land, don't look for a higher standard of medical education. Don't legislate for the schools: legislate for the people. If the twin sisters, education and civilization, have an influence or power, it should be used to control and enlighten and do for the ignorant what they cannot do for themselves. They are apt to look with distrust upon the educated, and the smooth-tongued charlatan fans the flame of their fears.

Get rid of those parasites—those barnacles that are not only degrading to the profession, but through their ignorance people our cemeteries faster than disease.

I have in my mind two or three men that educated themselves for the medical profession, gentlemen in every sense; but when compelled to recognize Dr. Ignoramus, to hear his praises sung by trumpet-tongued followers, divide profits with ignorance and deceit, see people, intelligent at least as the common run, recognize such blatherskites, and follow after them with as much enthusiasm and delight as a boy after fife and drum, throw up their profession in disgust and remain silent "lookers-on in Venice." The dead branches of ignorance are sapping the vitality of the profession.

There is little encouragement for a man to spend the best years of his life to educate himself for usefulness, and then have an ignorant, trumpet-tongued ignoramus sit down beside him equal before the law. "Equal?" Yes, superior; for in this State "ignorance of the law excuses no man," applies to *law* only: in medical practice the law does not punish a man for what he don't know (that is, as I read the law); and the man without a diploma is far the best off—nothing to lose, not accountable, everything to gain. If he loses, well, he has done as well as old M. D. was likely to; and if he gains, the shout will go up long and loud; he will be feasted and feted, and the horns will blow in indelible letters on every available board and barn in the country.

Give us a law that none but the competent shall handle medicine or prescribe for the sick. That will be encouragment enough and compulsory enough to fill the medical ranks with competent applicants.

Conneautville, Pa. ORSON HOUGH, M. D.

—The latest remedy for pruritus, when seated in the anus or vulva, is balsam of Peru. The *Brit. Med. Jour.* alludes to it as a new triumph in medicine.

NEWS AND MISCELLANY.

A Tribute to Lister.

Dr. C. G. Wheelhouse thus concludes his interesting paper on "*Pent-up Secretions*" in the *Brit. Med. Jour.*, January 3, 1885. Speaking of "FŒTOR," and the "ENTRANCE OF AIR TO PENT-UP SECRETIONS," he says:

"To us, in former days, here lay the great secret; we were well aware of that; and hence the carefully precise instructions that were given to admonish us to keep out the air from all our wounds, our explorations, our burns and scalds, and so forth; subcutaneous incisions; valvular openings, tunnelling into abscesses—anything, everything, to keep out the air!

"In all this, the first faint glimmerings of the dawn of better things may now be perceived; and, taken in combination with the fact that, having steadily fought the battle of the various dressings for wounds; the old and filthy poultices and cerates, under the influence of which I, when a dresser, have seen hundreds of maggots collect in twenty-four hours in an amputation-wound; the carefully neat, elaborate, painful, and baneful dressing by tight plaster; the much-vaunted 'water-dressings,' and 'dry-dressings,' and 'healing under scabs,' we found men, like Spencer Wells, seeking to protect wounds, alike from the decomposition of the exudations on the one hand, and of the air on the other, by covering them with 'pads of calcined oyster-shells and oil of tar,' with thick layers of cotton-wool, and so on, you may be sure that we were running with a fine scent, and were pretty certain to 'find' in the end!

"It was, indeed, often noted that air, if closely filtered, might pass into the cellular tissue of the body without doing more than simply temporary harm, as in the case of fractured ribs with penetration of the lung, in which air so filtered by passing through the air-cells, though actually distending the areolar tissue to the point of disfiguring the body beyond recognition, was nevertheless speedily re-absorbed, if not evacuated, and did no real harm.

"But to none of us, until Sir Joseph Lister arose, and drew aside the curtain from our ignorance, and showed us how the air we breathe, and which penetrates into the most hidden and secret recesses of our bodies, is laden with microscopic life and with germs, ready, the moment they alight upon a cultivable soil, to spring into life, and run riot in our wounds, our 'pent-up' secretions, was the revelation made that, to 'sterilize' that air was the only way in which septic mischief could be prevented, and surgery be rendered harmless.

"Towards this now attainable end, we of the nineteenth century have only advanced a certain distance on the way; but, to some of you it may be given to see the full fruition of our hope; and may you, gentlemen, bear your share in the good work."

An Anti-Vaccinator's Funeral.

The *Medical Press*, December 24, 1884, contains the following account of a most remarkable funeral that recently took place in London:

"No stronger evidence of the oft-repeated but much-abused dictum that 'this is a free country,' has been adduced of late than by the extraordinary funeral procession which passed through the principal thoroughfares of London on Saturday last. Here was an exhibition illegal in its essence, blocking the traffic, and appealing to ignorant prejudices against one of the most righteous laws ever promulgated. This so-called demonstration consisted of an open hearse with a child's coffin, preceded by a brake with a brass band playing the Dead March, and followed by a number of vehicles smothered in placards abusive of the Vaccination Act, and of every one not crazy enough to sympathize with their peculiar view of thought. Handbills were also freely distributed *en route*, and the police made no effort at interference beyond directing the crowds to move on. Truly, this is a free country! The following is a specimen of the literature forced into the hands of the public through which the procession passed:

"'Thou shalt do no murder—Exodus xx. In Memoriam, William Rd. Duncombe, aged six months, who was legally killed by vaccination. Was vaccinated on November 5, being perfectly healthy at the time. He was never well again, but sickened for death. His arm was much inflamed. On the 30th day of November a red rash appeared all over him. On 2d December he had four fits of convulsions. On the 4th of December the rash disappeared. Large lumps formed behind the ear and under the vaccinated arm. The vaccination marks had run into two deep and inflamed wounds, and he died in great torture on December 13. The mothers of five children legally killed by vaccination follow him to the grave, and ask of the people of England the repeal of the Vaccination Acts.'"

Specialties and their Relation to the Medical Profession.

Dr. L. Duncan Bulkley, of New York, read a paper on this subject before the American Academy of Medicine in August, 1884, which thus concludes:

1. The science and practice of medicine has, in company with other sciences, become so vast that no one mind is capable of fully grasping every portion of it.

2. Unconsciously, its various departments have become divided up, and from natural causes certain men have become prominent in various departments.

3. The so-called specialties in medicine are so great and extensive each, that particular or exclusive attention is now devoted to them, the study and practice in each branch being sufficient to fully occupy one's time.

4. The development of these branches has greatly increased the scope and extent of medical knowledge.

5. Every medical practitioner should be more or less of a specialist, excelling in some particular direction.

6. To properly follow and develop one of these specialties, the medical man should be particularly well educated, theoretically and practically, in general medicine as well as in his special branch.

7. This tendency to specialism in medicine can not be arrested; but the difficulty tends to solve itself, by the education of practitioners and students in these specialties, so that the majority of simpler cases shall be treated by them, while the more difficult and obscure cases will naturally fall to the specialist who refuses to treat other diseases and confines himself to the practice of a single branch.

Cannibalism.

The strange drama of cannibalism developed by the history of the survivors of the British yacht, Mignonette, has just come to an end in England. It will be remembered that the yacht foundered some months ago off the African coast, and the survivors, after a good many days of starvation and exposure, saw no hope of rescue, and, as a last resort, the captain killed a boy named Parker, and upon his flesh the party lived until help came. This is the barest outline of an awful story of suffering and starvation. The act was not deemed by the captain to be murder, but a measure of self-preservation, and was not concealed. A different view, however, was taken in England, and he was put upon trial for murder. The case attracted great attention from the unusual circumstances attending it, and much sympathy was felt for the accused.

The trial resulted in the jury finding the facts as above stated, but not determining whether they constituted murder or not. This was left to the judges, and Court of Appeals recently decided unanimously that the act was murder. The sentence of death by hanging was then pronounced by Lord Coleridge, but the black cap was not prescribed, showing a desire to relieve the disgrace of the mode of death. It was also said that if clemency was to be exercised, it must be by the Queen. This has just happened, for the telegraph announces that the sentence has been commuted to six months' imprisonment without labor. This action by the Queen will be received gratefully by the community, for the deed, while technically a murder, had so many extenuating circumstances as almost to lift it out of the grade of crimes. It is a matter for rejoicing that the cases are exceedingly rare when the choice has to be made between death and the destruction of a fellow creature.

A Novel Urinary Analysis.

Dr. M. N. Miller thus writes to the *Med. Record*, January 3, 1885:

A bottle of urine was sent me a few days since with a request for microscopical examination. The gentleman making the request wrote that the urine had been examined by an expert, but it had been done some months since, and he kindly enclosed a copy of the expert's report, which I have again copied *verbatim et literatim*, and send herewith. I do not know as it will contribute anything to the instruction of your readers—though it may amuse them.

"Report. The urine contains excess of phosphates, Epithelium, granular and Hyaline Casts, Albumen hematin Pus corpuscles, Some spermatoza cholestearine biliverdine uric acid in Large quantities.

"the urine is acid sp. G. 1005.

"This shows that you are suffering from Chronic Nephrosis of the Kidneys and Addison disease of the super Renal Capsules with a tendency to Bright's disease or Albuminuria.

"I shall not prescribe as you have your own doctor. I recommend Vichy water pretty freely.

"———."

The Insane Asylums of Canada.

The insane asylums of Canada are copying some of the objectionable practices of some of the asylums in the States, and are in need of reformation of a decided kind.

Judge Jette, of the Supreme Court at Montreal, after a suit pending for several months, has directed the discharge from the Longue Pointe Asylum of Mrs. Rose Lyman, who has been incarcerated there for three years. The facts as stated in the papers are as follows :

"Three years ago her husband had her incarcerated in the institution, the superintendent certifying to her insanity. She has since been confined in the most refractory ward, although the resident physician testified on oath that she was sane when admitted. When the fact of the gross outrage became public, citizens all over the Dominion subscribed a fund to enter the suit for her liberation. Mrs. Lyman has brought suit for separation from her husband, and also for $10,000 against the Government Medical Superintendent for signing the certificate of her insanity."

The Oleomargarine War.

The oleomargarine war waxes furious in some of the States, and in New York the last phase of the contest is a decision by the Supreme Court in the Second District that the law on the subject passed by the last Legislature is constitutional. There was one dissenting judge, and the case will be appealed, as the questions at issue are of a good deal of public importance. Much has been recently claimed for the "police power" of a State in the way of preventing trades or manufactures alleged to be injurious to the public, and it is important that some clear statement of the law should be made.

It is unquestionable that the manufacture of dirty or impure oleomargarine can be stopped legally, and also the offering for sale of oleomargarine for real butter ; but the point to be absolutely settled is whether all manufacture of the article can be prohibited in order to secure this object.

The progress of the case will be watched with some interest.

Medical Education.

Before the Midland Medical Society (England) December 3, 1884, Mr. Haslam read a paper on medical education, in which the question of what education the student should have before commencing his medical studies was discussed. Many students at present entered at a hospital with little or no knowledge of such subjects as chemistry, botany, or physics, and were consequently unable to study at once, with advantage, either physiology or chemistry; moreover, they had not learnt how to work at scientific subjects, and so lost much time on this account. It was suggested that much benefit would be derived from having a medical college, where boys intending to study medicine could enter, after having passed one of the preliminary examinations, and spend a year acquiring some knowledge of these scientific subjects that would be of use to them later on ; they would then be able, on entering at a hospital, to study with greater advantage the various medical subjects met with there, and would have more time to devote to attending hospital-practice.

The Jefferson Medical College Hospital.

The Trustees of the Jefferson Medical College Hospital presented their annual report January 17, 1885, which sets forth that during the past year 12,618 patients were treated, of which 1,290 were in the wards of the hospital, and 11,328 in the out-patient department. There were 33,414 visits made to charity patients. The above were attended by 41 physicians and surgeons, of whom 36 were on duty daily. During the year 27,866 prescriptions were filled in the dispensary. The report contains the gratifying statement that the mortality of the ward cases, including accidents, was but 45 to 1,000.

The Graduating Class of Jefferson College.

The graduating class of 1885 of Jefferson Medical College held a meeting in the lecture-room of the college, January 17, for the purpose of organizing the class prior to graduation. The following officers were elected:

President.—Dr. J. D. Orr, Pennsylvania.
Secretary.—Dr. J. E. Oliver, Missouri.
Treasurer.—Dr. J. C. Barr, Pennsylvania.

Items.

—An official register of physicians and midwives of Illinois has been issued by the Board of Health of that State.

—By the recent charity bazaar held at the Natatorium, in Baltimore, for the Nursery and Child's Hospital, $6,500 net, were realized. This will be utilized in furnishing the new wing of the hospital.

—According to the Commissioner of Education, General Eaton, there were 8,681 medical students in this country in 1873, and 15,151 in 1882. The medical schools increased during the same period from 94 to 134.

—According to the *Jour. Am. Med. Ass.*, December 13, 1884, Prof. Frerich states that interstitial hypertrophy of the liver is always due to one of four causes: 1. Alcohol. 2. Syphilis. 3. Malaria. 4. Transmitted inflammation from the gall-bladder.

—For a number of years it has been the custom in Dublin to have an annual foot-ball game the day before Hospital Sunday for the benefit of the Hospital Sunday fund. In this country the advantages accruing to hospitals from foot-ball games are chiefly clinical.

—A Parisian jeweler has been fined fifty francs for homicide through imprudence, and ordered to pay 150 francs damages to the parents of a child whose death he had caused by piercing its ears for earrings too high up, the operation having been followed by inflammation.

—While other professions are laboring, organizing, scheming, for their own advancement and for the establishment of their power over society, ours has so completely forgotten its common interest in individual sacrifice, that to this day it remains, as has been well described for all practical purposes, a disorganized rabble.—*Asche.*

—Dr. Louis A. Duhring reports in the January issue of the *American Journal of the Medical Sciences*, a marked example of what he has described as dermatitis herpetiformis. The history of the case, including the cause of the disease—a violent shock to the nervous system—is both interesting and instructive.

—Spasm of the tongue, occurring as an independent affection, is recognized to be quite rare. A case has recently fallen under the care of Dr. Edmund C. Wendt, which he records in the January number of the *American Journal of the Medical Sciences*. The history of the case shows the decidedly beneficial action of galvanism in localized muscular cramps.

—Dr. Atthill, of Dublin, uses the following lotion in pruritus vulvæ, and it is also applicable to pruritus ani, a pledget of cotton being soaked in it and passed up the anus and left there till the next defecation, when it was removed:

℞.		
	Acid carbolic,	gr. xx.
	Tinct. opii.,	℥ ss.
	Acid hydrocyanic dilut.,	℥ ij.
	Glycerine,	℥ ss.
	Aquam ad.,	℥ iv.

—Dr. H. Lawson, of Cuthbert, Ga., who is described by the editor of the *Southern Medical Record* as "a modest though worthy practitioner," announces a cure for cancer. It consists, as we understand, in the heroic use of arsenic, combined later with caustic applications. In one patient suffering from epithelioma on the left temple, one-fourth of a grain of arsenious acid was given, and gradually increased to three-fourths of a grain.

—The following, suggested by a retired army surgeon, is going the rounds of the press as a cure for gonorrhœa:

℞.		
	Zinci sulph.,	
	Ext. belladonnæ,	āā grs. xx.
	Mucilag. acaciæ,	℥ j.
	Aquæ,	ad. ℥ viii. M.

Sig.—A teaspoonful to be injected frequently. An ointment of opium and belladonna also to be smeared along the perineum and crus penis at night.

—The characteristics of the cholera epidemic of 1884, as summed up by a committee of the Académie de Médecine, composed of M.M. Dujardin-Beaumetz, Hardy, and Proust, are as follows: 1. Relative benignity, corresponding with the regular decrease in the gravity of cholera epidemics since 1832. 2. Absence of special premonitory constitution, as shown by choleriform diarrhœas. 3. Uncertainty, or at least great variability, in the mode of propagation. 4. Many facts showing that the disease is very contagious; many others showing the contrary.

—The violent anti-vivisectionist, Ernst Heinrich von Weber, has recently been sentenced to eight weeks' imprisonment. In the journal entitled *Der Thier- und Menschenfreund*, of which he is the editor, he published, under the heading "Vivisection of a Man," a statement that about eight years ago a Jewish physician of Osnabrück had made a post-mortem examination of a man while only apparently dead, and therefore had performed vivisection on him. Dr. Pelz, who had performed the post-mortem in question, summoned him before a court of justice with the above result. A clergyman of Munster, also, who was the author of the article, was sentenced to six weeks' imprisonment.

—Mr. Meredith, of London, publishes fifty cases of ovariotomy in the *British Medical Journal*, the work of three years. Forty-six of the patients recovered, making a mortality of only eight per cent. The operations were all performed under spray, and with due antiseptic precautions, to which course the writer attributes the fact that he was able to dispense with the drainage-tube in all but three cases. Mr. Meredith urges an argument against hyperpyrexia being due to the absorption of carbolic acid the fact that in forty-two of his cases the temperature did not exceed 102° F. Nine other cases of laparotomy for various causes are appended to the report, of which one was fatal. These statistics are valuable as the writer is well known to be Mr. Knowsley Thornton's assistant and able exponent of his methods.

OBITUARY NOTICES.

MARCELLUS WHITEHEAD, M. D.

Dr. Marcellus Whitehead, who had been a successful practitioner of medicine in Salisbury, N. C., for upwards of forty years, died of Bright's disease, January 2, aged 64 years.

JOHN PRESTON WOOD, M. D.

John Preston Wood, M. D., of Lamar county, Texas, died Nov. 12, 1884, of locomotor ataxia. Dr. Wood was born in Amelia county, Va., April 4, 1816, and began the study of medicine at the Medical Department of the University of Virginia in 1836. He graduated from the Medical Department of the University of Pennsylvania in 1840. He removed to Texas in 1854, where he continued in the practice of medicine until soon after the war closed, when he retired from practice, owing to disability. He was highly respected, and his loss is mourned by many friends and admirers.

MARRIAGE.

RUSH—PIERCE.—December 21, 1884, at the residence of the bride's father, Mr. William Pierce, by Rev. Dr. Thompson, Dr. A. J. Rush and Miss Laura Pierce, all of Delta county, Texas.

DEATH.

VAN SLYCK.—December 27, 1884, in Brookline, Mass., of apoplexy, Annie E. C. Van Slyck, wife of D. B. Van Slyck, M. D., aged 51 years and 5 months.

Lecture.

ABNORMAL POSITIONS OF THE HEAD—WHAT DO THEY INDICATE?

BY EDWARD BORCK, A. M., M. D. SURGEON.

Of St. Louis, Mo.

A Clinical Lecture Delivered before his Private Class of Practitioners, with a Case of Dislocation of the Cervical Vertebræ.

Gentlemen: Instead of continuing our study of the injuries of the hand, we shall to-day take up a very interesting subject, about which you can find, so to say, nothing in the journals and very little in the text-books. It is *abnormal positions of the head.* I mean to speak of cases which are of a complicated nature—cases where the different positions of the head will serve as a valuable diagnostic sign in determining the ailment of the patient. It so happens that I am able to bring before you several cases to-day, to illustrate practically what I have to say. You may know at once, that in any mal-position of the head we have to consider the conditions of the neck, both in its muscular and bony structure.

Look carefully at these four little patients sitting before you, and remember what I have so often repeated, that before you proceed to make any manual examination you should precede it with a careful ocular examination. Observe closely, and first learn all the conditions you can with your eyes. Now, how are we to group these conditions for clinical purposes? The answer is, first into cause, and second, progress; for if these conditions were *not* brought on gradually they would lead our minds at once into quite a different channel, and our examinations would end perhaps with a wrong conclusion.

Let us take the first case. Here is a little boy nine years of age. Look at the position of his head. This is a chronic case. He has carried his head for sometime in this stiff manner that he might avoid all rotation, or any movement forwards and backwards. Stand quiet and straight, my boy; now turn your head towards the window. We see he cannot do this, without turning around his whole body. Now, if we knew nothing about the history of this case, how should we begin to make a correct diagnosis? We should necessarily make some anatomical observations, and ask, Are the causes of this abnormal position produced by muscular disease, by disease of the bones, or by disease of the joints? We may put it into still a shorter phrase, and ask, Are any of the active or passive structures of motion here implicated? This simplifies the question, and will serve very well for clinical examination.

Now to our case. The mother tells us that about a year ago this boy began to complain of difficulty in swallowing, and something like constriction around his neck; that he had a cough which continued in spite of cough mixtures. She gave these for some time before she noticed the stiffness of his neck. Then very severe pain came on, and it continued until the present stage of development.

Now, if such a case presents itself to us in the early stage, and after careful physical examination of the chest, and laryngoscopical examination, we can detect no disease of the chest or larynx, sufficient to account for these symptoms, then let us direct your attention to the nerves

that make their exit from the spinal canal at the points opposite to the usual site of the disease. Examine carefully the spinal column in the manner that I have previously shown you; and do not forget that after all, the symptoms enumerated may be produced by reflex nervous irritation.

Here, in this patient, we can observe that there is a swelling upon the left side of the neck; that side is convex; there is pain under pressure, and we can feel a seeming enlargement of the bony part below. This depends, however, upon the swelling of the soft structures united to the bony structures. The head of this boy is now inclined to the right and bent forward, and the sterno-cleido mastoideus on the right side is relaxed and concave. In the progress of the disease this picture will be reversed; the head will then incline to the left side, on account of the bony structures upon that side being destroyed by caries. The diseased left side will then be concave and the right side somewhat convex; at any rate, it is to the concave side we have to look for the destruction going on of the bony parts. In this case the swelling and pain give us the indications of what the disease is.

During the different stages of the disease we shall meet with different symptoms and different diagnostic signs. In some cases we shall find a torsion of the vertebral column, and can feel a prominence in the throat of one or the other vertebra, like steps. In others we may distinctly feel a prominent, painful spinous process. I cannot go into details about this to-day, but during the course, we shall take up this study again. The result of our diagnosis is that this is a case of Pott's disease.

"Pott's disease" begins first as caries of the vertebræ or caries of the joints of the vertebræ. We shall not always be able to tell where the disease first made its appearance—whether in the bones or in the cartilage. Many satisfy themselves by saying, "This is caries or ostitis or periostitis of the cervical vertebræ, depending upon tuberculosis or a scrofulous diathesis." I believe, however, that the majority of these cases result from injuries. We shall learn more about that at some other time.

Now, let us look at this little girl; she is about eleven years old. Observe the very peculiar position, or rather carriage of her head and her distressed physiognomy. Bend your head forward and backward, my child. You see she accomplishes this slowly. Come, sit upon this table; now try to lie down, please. You see she immediately brings both hands to her head to give it support. Now, arise. You see, again both hands are brought to the head to support it. These symptoms came on gradually.

From what you have seen, what would be your diagnosis? You would rather that I should make it. All right; I say there is disease of the second cervical vertebra. Why? Because the rotary movements are accomplished only by the atlas turning upon the dentata, and there are here no visible signs present such as we observed in the previous case; the parts lie too deep to admit of any prominent external indications. The forward and backward motion is accomplished between the occiput and atlas. This the patient can do; therefore there can be no disease at that point.

This affection has been called "Rust disease," because Prof. Rust first described it. It is, however, only a special case of "Pott's Disease." The patient's instinct tells her to support her head to save it from harm. She is in great danger of fracturing the odontoid process, thus injuring the spinal cord and producing death at once. We find the same symptoms when the odontoid process is affected with carcinoma or sarcoma, but the pain in that case will not cease when the patient assumes the recumbent position.

Whenever we have a case where the patient cannot rotate his head, and supports it with his hands during the act of lying down or rising up, we can rest assured we have some disease or injury between the atlas and dentata. Of course, the severity of the symptoms will depend upon the amount of injury, but in no other disease or injury will we find such positive symptoms. We may have a complication of other injuries or diseases in addition to these symptoms, that may not depend upon the injury between the atlas and dentata. They may be of quite a different nature, but no matter what the complications are, we must not be misled and overlook this important point. Ability to make a forward and backward motion of the head, with only a partial or perhaps complete absence of rotation, is our guide to the diagnosis of injuries or disease of the dentata.

Now we place on our patient this temporary cravat. By next Wednesday her apparatus will be made, and we shall apply it, and give her at least temporary relief. I say temporary, because sooner or later these unfortunates will succumb suddenly by fracture of the odontoid process.

Now let us examine the next little girl. She is about six years old. Her mother states that she had this distortion from birth; otherwise she never was sick. But for the last two years this

deformity seemed to grow worse. Her head, we see, is sunk towards the left side, and rotates towards the right side. We see that the sterno-cleido-mastoid muscle of the left side is very prominent, and is shortened by contraction. In all these one-sided contractions, we observe that the ear is nearer the shoulder on the diseased side and the chin is turned towards the sound side. The occiput is also a little lower. Here we have a case of torticollis. We shall meet this same picture in some cases of "Pott's disease" where the disease has been cured with a scoleotic curvature of the cervical vertebræ. How do we make the differential diagnosis? The question is this: Are the contractions of the muscles primary or secondary? A single glance will answer our query. In the case before us we see the head is bent towards the one side and rotated towards the other. If this distortion had been produced by "Pott's disease," the head would also be bent forward, but not rotated to the other side. Primary contractions of the sterno-cleido-mastoid muscle are congenital; secondary contractions are acquired.

These symptoms may, however, be present in a hysterical person, and we must be careful not to be deceived in such a case, for the contractions then depend upon spasms.

This child will be brought here again next Wednesday. I shall then divide this muscle and show you how the head is to be kept in a normal position.

Besides these conditions that we have observed in the three cases presented, there remain a few other abnormal positions of the head valuable for clinical purposes. They are characterized by their sudden appearance. Of course, I mean injuries such as contusions, concussions, luxations, and fractures of the cervical vertebræ. Here let me call your attention to acute rheumatism of the muscles of the neck, which is also a cause of an abnormal position of the head, and though the latter is quite a different disease from the former, nevertheless it deserves the attention of the surgeon, because very often rheumatism (sudden pain of the muscles) occurs in conjunction with slight injuries; and the mal-position of the head produced by acute rheumatism presents almost the same appearance to the eye as if it were produced by injuries, and the two are very often mistaken, the one for the other.

Now, let us take a look at this little miss. She is about twelve years old, of a healthy constitution; she lives in the country. Her parents brought her here this forenoon, with the following history: While playing during recess at school, no doubt romping about with the other children, she felt all at once a quick sharp pain in her neck, her head turned to the left side, and she could not move it. This is rather a unique case, and the interesting point is this: it occurred about two weeks ago; she has been rubbed with liniment, warmth has been applied, etc., etc., all to no purpose. She now has difficulty in swallowing, and her right arm begins to feel numb and somewhat lame. You see that her head is turned to the left side, the left side of the cervical vertebræ is concave, but the muscles on this side are not contracted; the right side is convex. No movement of the neck and head can be executed. You see the left side is somewhat flushed, the right side is pale. This tells us that the vaso-motors are implicated. Here at the highest point of convexity, it is very painful under pressure. Below this point here, I feel a transverse vertebral process. She also has strabismus. The left eye is divergent, the right convergent. What is the diagnosis? Well, we have here a partial luxation of the fourth cervical vertebra, or rather the upper four cervical vertebræ.

What are the differential points between dislocation and rheumatism? In dislocation the muscles are perfectly relaxed; in rheumatism they are contracted; at least they are hard and stiff, and no perceptible prominence of the spinous processes is present. If this is not satisfactory to you, chloroform the patient. As long as the luxation is not reduced, there can be no motion. In rheumatism you can make passive motion at once.

We shall now try to reduce this dislocation, and I shall do this by suspending the patient carefully by the head, and by manipulations. The parents have been informed of the hazard connected with this operation, and have given their consent, and I ask of you not to become alarmed if you see the patient turn blue, and probably suspend breathing for a second. Keep perfectly quiet and tranquil—a virtue the surgeon should always possess.

The child was suspended by the head, and the reduction speedily accomplished.

Ah! this is fortunate. You see the reduction was comparatively easy. Did you notice how blue the child turned for a moment? She can now move her head. The strabismus has disappeared. How easily she breathes now! Now, don't cry, my child, you are all right. We shall now apply, as a matter of protection, one of those temporary cravats and let her wear it for a fortnight.

Cases of dislocation of cervical vertebræ are very rare, at least very few are on record. This is the second case I have met with in my practice, and the first in which I have used this method of reduction by suspending the patient by the head. Luxations between the head and the atlas do sometimes occur; also luxations of the atlas; they are, however, very rare. But very few cases are on record. We may meet with the lateral and bi-lateral dislocation of all of the vertebræ, but with a little thinking, you can draw for yourself an imaginary picture of the position that the head must necessarily assume when such injuries take place.

Contusions of the head may simulate bi-lateral luxations backwards. In such cases, examine the muscles of the back of the neck, and remember, if they are spasmodically contracted there is no dislocation. In paralysis of the muscles of the back of the neck, the head will be drawn forwards and the chin be pressed upon the sternum.

Besides the mal-positions of the head pointed out already, there are other forms which are deserving of our attention for a few minutes. For instance, in dislocation of the shoulder, the patient bends his head toward the injured side. A simple furuncle may be the cause of the head being held perfectly motionless. A swelling or tumor may produce distortion of the head. These secondary abnormal positions may not exactly help us to a direct diagnosis, but if we pay attention to them, they will guide us into a positive direction. In a case of stenosis of the air-passages, we naturally think of croup, but instead of finding the head bent backwards, as children invariably do in croup, it will be bent forwards and a retro-pharyngeal abscess be the cause of the trouble. In a malposition of the head caused by paralysis the muscles are relaxed and atrophied.

Let us finally remember that abnormal positions of the head may depend upon neurotic causes. Spasm of the deep-seated muscles will throw the head backwards. Spasm of the superficial muscles will throw it forwards. The diagnosis can always be made, for the muscles here are contracted. By the contraction of an old cicatrix, such as is left after a carbuncle or burn, very peculiar positions of the head are produced.

A good deal more might be said of the different mal-positions of the head, as a diagnostic sign, but we have gone already far beyond our time, and I hope you have been interested, and that the cases proved instructive to you. I thank you for your attention.

Communications.

INVERSE TYPE OF TEMPERATURE IN TYPHOID FEVER, WITH A REPORT OF TWO CASES.

Temperature Peculiarities in Epidemics, with a Report of Seven Cases in One Family.

BY W. C. HOLLOPETER, M. D.,

Of Philadelphia.

(*Continued from page* 104.)

The point worthy of attention is, that the temperature in this nearly fatal case remained nearly the same for the morning and the evening record. Immermann tells us, that only in cases in which the fever is very severe, and the absolute temperature very high, that the difference is less, and does not exceed three-fourths of a degree.

Case 2. The second member of the family to fall ill was the mother, æt. 32, who had acted as constant nurse to the daughter. It was thirty-four days after the daughter was taken sick, and the daughter was yet in bed, when the mother was compelled to relinquish her duties. I might state that the mother was on the eve of her confinement, that she watched and waited on her sick child up to the hour of her illness, she passed safely through her labor, remained in bed one week, was up and around the house for *five days* before she had any decided symptoms of fever. She had a slight chill, which was soon followed by a temperature of $104\frac{3}{5}^{\circ}$ in the evening. This was, however, the highest point reached. She had no delirium, nor vomiting. Bowels were opened daily, but not unnatural. The temperature remained high for over a week, ranging between 103° and $104\frac{1}{2}^{\circ}$. It had a gradual decline for over thirty-six days, when it reached normal, without any unusual variations between the morning and evening record. Convalescence was very slow. The record was a typical temperature record from the second week of typhoid, yet much milder than that of the child. The puerperal state did not seem to modify the course of the fever or endanger the life of the patient.

Case 3. The husband and father, æt. 36, a house-carpenter by trade, rugged and compactly-built German, was next on the list. He was a perfect type of physical perfection. He continued his work up to the hour of taking to his bed, February 10. He had complained of a cold, headache, and sore throat for two days previously. I found him, on the morning of the 10th, with a temperature of $105\frac{3}{5}^{\circ}$, pulse 90, respiration 20, dry, hot skin, dark and injected countenance, bowels

loose, abdomen flat, very stupid and sleepy. In this case the pulse was full and regular, never going above 90, and yet for over two weeks his temperature lingered around 105°, with profound stupor, alternating with the wildest delirium. He had during the second week constant *subsultus tendinum*, and frequent involuntary movements of the bowels. On the twenty-second day of his illness he suffered a hemorrhage of fully eight ounces. He had several smaller hemorrhages previous to this date. On the sixteenth day his temperature fell to 101⅕°, remaining under 102° with but one exception, when it ran up to 103°. Temperature did not reach normal until the thirty-eighth day.

Case 4. Caroline, æt. 5, was taken ill on January 13, three days after her mother. She started with a temperature of 104⅗°. She had been listless and stupid for a week preceding her complete prostration; during the prodromata I registered her temperature twice daily, but did not find the thermometer above 100°. Two days from the last date the fever had reached 105⅖°. From this point on it was a gradual decline for twelve days, when it as gradually climbed up to its old figure of 105⅖°. This intermitting type continued for forty-two days, when it fell below 100°, and I ceased to make a record. The case was one of unusual severity, frequently losing large quantities of blood by the bowel, yet constipation was the rule throughout the illness. Epistaxis was also constant, the face being stained daily with blood; low delirium existed for over two weeks. The patient was in bed for over seven weeks.

Case 5. Katie, æt. 10, had a temperature record of her own—a marked difference existing in this case from the others. Above 104⅖° to start with, reaching 105° the same evening, remaining above 104° for *three days*, then gradually declining for three days, when it assumed again the upper tendency, holding it for three days, then came a rapid fall. This intermittent character in the temperature continued for thirty-two days.

This case was obstinately constipated throughout her illness, and was but slightly delirious. Recovery slow, six weeks in bed.

Case 6. Pauline, æt. 14, an unusually well-developed girl, and the last case which I deem of sufficient interest to record in the history of this family epidemic, will also illustrate a different phase in temperature irregularities. Three of the children before they became actually sick were noticed to have a weary, listless expression, did not manifest interest in their play, showed a decided preference for the house, which was contrary to their usual habits.

I registered the temperature of two of the younger children for a week or more before they were stricken down, and I did not find an elevation of temperature but slightly above normal, unless the temperature was taken in the evening, when it was generally near 100°. Taking into consideration the daily fluctuation in health, which is always higher in the evening, I could scarcely draw the line between the normal evening elevation in health, and the insidious approach of the fever. With Pauline I still endeavored to anticipate the onset of the disease. Acting on the suggestion of some of my professional friends, I commenced to register her temperature nearly two weeks before I perceived any indications of her being the next to fall sick. I might anticipate any theoretical conclusions likely to find lodgment in your minds as to the causation, by stating that the girl had been employed in a dry-goods store, and was brought home to take charge of the sick family. Upon her devolved most of the washing and cooking for the sick. While the younger children were out of the house nearly all day at play, she was busy with household duties, and was in this way more exposed to the infectious disease than her younger sisters, who seemed to contract it so readily. I found it most convenient to take her temperature at the time I visited the other members of the family, *i. e.*, between nine and eleven in the morning, and eight and nine in the evening. I never found her temperature above normal, until within four days before she was compelled to take to her bed. Three days before her prostration, the thermometer registered 102°, normal the following day; second day it was 101⅗°; the following day it ran up until it reached 104⅖°. Her temperature continued high for over ten days, ranging from 103° to 105°; then assumed the intermitting character so frequently noticed in the record of the other members of this family, after which the fever record had a gradual decline. By anticipating her attack of the fever, and registering her temperature for over a week, three days in which her fever was above normal, gave us part of the ascending scale of Wunderlich—yet does not supply the gradual ascent and the lengthened arc of the semicircle, which should describe the model typhoid temperature record.

I have hinted that the cause of this epidemic had a tangible existence. While it is not the object of this paper to touch upon the etiology of typhoid, yet it may not be without interest to mention the environments of this fated household. It is unusual to have seven cases of typhoid occur

in one family, and follow each other in such rapid succession; yet not until the third member of the family was prostrated, could an adequate cause be found.

The head of the family was an industrious carpenter, who resided, with his wife and five children (two older girls were not living at home), in a two-storied, four-roomed house, near Thirteenth and Columbia avenue. The house was quite comfortable for a small family, but not so for this one; hence they were crowded. Yet I have seen families packed in, and live free from disease, when there has been actually more to a room than in this family. The cellar was dry, drainage in a fair condition. A vacant lot of enclosed ground intervened between our family and the nearest neighbor on the north. This neighbor on the north was in the milk business, and for his convenience, he had excavated a pit in the vacant lot adjoining our family's cellar-wall, four feet deep, into which he had dumped the rubbish of the yard. The rain and snow, falling upon the decomposing mass of organic material, soon found its way through the intervening stone-wall, percolating its liquid poison into the cellar. This filth, while not all times sufficient to be recognized by the sight, was more frequently perceptible to the sense of smell. The pit could in no way impregnate the drinking-water of the family, for, as a precaution, I had all the water that was consumed for that purpose brought to them from a distant neighbor.

While we have mentioned the exceptional in the temperature record, we may also entertain a doubt of this rubbish-pit being the only factor in the family illness. The first case in the epidemic, Mary, æt. 13, was employed in a store; hence she was not in the atmosphere of the house as long as the mother, who was the only one who constantly lived in the poisoned house, and yet second on the list, and, while she had a severe attack, her illness was not so prolonged as the first. Again, Pauline, the eldest girl, came from another family, in perfect health, resided for three months in the infected house, exposed to every form of contagion, and was the last to succumb to the disease; and when finally she was prostrated, the fever ran a comparatively mild course.

In directing your attention especially to the peculiarities of temperature in the foregoing cases that ended in recovery, I wish now to contrast them with one that, while the temperature was under control, and lower than any of the foregoing, yet, without complications, it ended fatally.

A finely-built young man of 27, regular, but rather full habit, first complained, August 1, of intense headache, backache, indifferent appetite, and general disinclination to exertion. He left the city, against the wishes of friends, as well as myself, for a trip through the South. On the 3d he was taken violently sick; sent home, reaching the city August 4. At my first visit, same day, at 12 m., temperature was 104°; at 8 p. m., 104⅘°. On the sixth day he lost consciousness. His delirium was wild and pugnacious; constant mutterings. At the same time his temperature fell below 104°, and remained below for over a week. On the tenth day his temperature reached 104⅘°. From this point it fell, and remained under 103° until the fifteenth day, when it ran up to 104⅘°, at death.

It is unusual to find patients unconscious when the temperature is so easily under control. In this patient the only antipyretic measure used was the cold bath. None of the symptoms of this case were as severe as the group occurring in the epidemic; yet this case terminated in death, while all of the others, indifferently nursed and badly surrounded, made good recoveries.

While it has been my principal object to record these cases of typhoid, as departing in a measure from the temperature law of Wunderlich, I wish to call your attention incidentally to the following facts:

1. Six of the group of cases noticed in this paper were children, yet we had a severe course of the fever, and the temperature record commenced high, showing frequent irregularities. Wunderlich states, that in children, particularly in the younger subjects, the course of typhoidal temperature is somewhat irregular. The commonest of these irregularities is its extreme mildness; yet the temperature rises in the first days to a higher average than in adults; it passes more quickly into the remitting period, and defervescence is less protracted, but complications often occur, closely indicated by the temperature.

2. In the nine cases of typhoid, including mild as well as severe examples, we had four cases of intestinal hemorrhage. An unusually large percentage. Systematic writers on fever regard intestinal hemorrhage as a rare and grave symptom. While Liebermiester states that there is not a single symptom belonging to typhoid which can be characterized as pathognomonic, yet a tendency to diarrhœa is quite frequent and intestinal hemorrhage quite rare, in our cases we found the bowels confined in over half of the cases.

Dr. Broadbent looks upon constipation in typhoid as of sufficient importance as to entitle the fever to a distinct variety.

REMOVAL OF UTERUS AND OVARIES BY ABDOMINAL SECTION, FOR FIBRO-MYOMATA. DEATH ON TWELFTH DAY FROM SEPTICÆMIA.*

BY J. M. BARTON, M. D.

Mrs. K., æt. 31 years, was brought to me last September, by Dr. M. B. Dwight, of Jersey Shore, Pa. She was very pale, the face and lips being entirely colorless; indeed, the appearance of the patient suggested the presence of malignant disease. She had to be carried to her room on her arrival in this city. She had been losing more blood than she should for several years, and for several months she had a daily loss, frequently in quite large amounts, and was losing strength rapidly.

On examination, a large, hard, smooth, and freely movable tumor, evidently the uterus, extending three inches above the umbilicus, was found; by the sound, Dr. Dwight's diagnosis of a sub-mucous fibroid with extensive uterine attachments, was readily confirmed.

As the uterus was entirely out of the pelvis, as the attachments of the tumor occupied more than three-fourths of its entire circumference, and as the remaining uterine wall was much thinned, removal by the vagina was plainly impossible. I advised extirpation of the ovaries, if accessible, or of the entire uterus, if, on exploration, it appeared preferable.

The patient returned to her home, as she preferred to have the operation performed there, to which I agreed, as I considered the mountain air much more favorable for operation and after-treatment than the wards of a general hospital.

On September 30, I visited Jersey Shore, and removed the growth, assisted by Drs. Dwight and Cline, of that place; Drs. Detweiler and Youngman, of Williamsport; Dr. Armstrong, of Lockhaven; and Dr. Orville Horwitz, of Philadelphia.

Thorough antiseptic precautions were taken, the hands of the operator and assistants were washed in carbolic acid solution, all the instruments and ligatures were immersed in a similar mixture, the sponges were washed in a warm solution of the same acid, the abdomen of the patient was washed first with turpentine, then with soap and water, and lastly with carbolic acid solution.

I made an incision through the abdominal wall, midway between the umbilicus and pubes, about two and a half inches long, through which I readily drew the right ovary; the left, however, could not be reached. Finding the uterus free from adhesions, and movable, we decided to remove it. I increased the incision until it ran nearly from ensiform cartilage to pubes, carefully checking all hemorrhage by forceps and catgut ligatures before opening the peritoneum; the uterus was readily lifted from its bed and placed upright, the left broad ligament was attached posteriorly, and the left ovary laid against the spine, showing that it could not have been reached through the original incision. The intestines were held away from the uterus, and supported by large flat sponges, wrung out of warm carbolic acid solution. The broad ligaments were tied in sections with carbolized silk and Thomas's large clamp placed upon the neck of the uterus.

Surrounding the parts with sponges, to prevent blood entering the peritoneal cavity, into which so far none had escaped, the uterus and both ovaries were rapidly removed; there being but little tension on the pedicle, we decided to treat it outside.

The stump was trimmed so as to leave but little projecting above the clamp; it was transfixed by a large pin, and was seared on its cut surface by the actual cautery, the wound was closed by the interrupted suture introduced from within in the usual manner; it was not found necessary to make the "toilette of the peritoneum," as, thanks to the care of my assistants, no blood had been allowed to enter that cavity, and, indeed, but little was lost during the entire operation.

The uterus was seven inches in diameter, and nearly a sphere; it was occupied by a single fibromyoma, which was attached to the entire uterine walls, with the exception of a narrow channel, about two inches wide, running from neck to fundus; on section, it presented the usual appearance of such growths, except in its centre, where it appeared to have undergone sarcomatous degeneration. This suspicion was subsequently confirmed on microscopical examination.

The after-treatment of the case was in the hands of Dr. Dwight, from whose very complete notes I take the fallowing points:

The evening of the operation the temperature rose to 102.5°, the pulse to 120; under opium suppositories and occasional hypodermics of morphia, the patient was quite comfortable; she took nothing whatever into the stomach except small quantities of hot water, and had no vomiting. On the second day the thermometer rose to 104°, the maximum temperature observed.

On the third day she took some barley-water

*Read before the Philadelphia County Medical Society, December 17, 1884.

and in the evening some beef-tea, the general condition being improved and improving still more the fourth day.

On the fifth day (October 4) the bowels were moved by an enema: opium stopped; beef-tea, brandy, and warm milk were taken freely; the patient was quite comfortable.

On the sixth day (October 5), patient rested well during the night, takes warm milk every three hours; pulse stronger, 120; temperature, 101°; patient looks quite bright; natural movement of the bowels.

The notes of the seventh, eighth and ninth days are almost identical with the last one read, except that stitches were removed, and on the ninth day there is considerable pus coming from wound, and some swelling of the right parotid gland.

On the tenth day the swelling of the parotid gland increased; there were evidences of systemic poisoning; and on the evening of the eleventh day she died.

At the autopsy, there was no inflammation of intestine, there was no pus found in lungs, liver, or kidneys, though there was some in the abdominal cavity. This had probably entered a day or two before her death, and from it the blood-poisoning, which proved fatal, arose.

Hospital Reports.

PENNSYLVANIA HOSPITAL CLINIC.

BY DR. R. J. LEVIS, SURGEON.

Reported by C. Levis Bower.

Fracture of the Lower End of the Radius.

I bring before you to-day a fracture of the lower end of the radius. There are no fractures of bones of which a complete comprehension is more generally needed than those of the lower end of the radius. There is no other class of fractures in which, with the treatment ordinarily pursued, the apposition of fragments is so liable to be imperfect and to result in deformity with painfulness, defective innervation, and impairment of the utility of the limb. Perhaps there are no fractures which so often fail to be even recognized as these fractures; and I am convinced that their peculiar nature and the indications of their treatment are not sufficiently understood. I have seen more instances of dissatisfaction of patients with their medical attendants in regard to the results of these peculiar fractures than of any other, and I think that it must be the experience of every surgeon in active practice to be frequently appealed to an account of the more or less permanent disablement of forearm, wrist, and hand which so often follows the treatment as generally practiced. Such deformity and disability have also in a number of instances led to litigation in which the reputation of the attending surgeon has suffered discredit. That the result of the usual treatment of fractures of the carpal end of the radius, even by the most experienced surgeons, is considerable deformity and consequent disability, is admitted by the best surgical authorities. I will read what some of them say on the subject. Hamilton, in one of the editions of his work on fractures, states that of ninety-two instances of fracture of the lower third of the radius, sixty-six could not be claimed to have been cured free from perceptible deformity or stiffness about the wrist-joint. In some of these cases examined by him after the lapse of from one to twelve years, the wrist- and finger-joints remained quite stiff.

Prof. Gross said that this fracture is "often followed by permanent deformity and impairment of the functions of the wrist-joint," and "that from three to six months always elapse before the patient will have anything like a good use of his hand and fingers, owing to the remarkable tendency, in every case of such injury, in the resulting inflammation to extend to the synovial membrane of the digital articulations and sheaths of the tendons."

R. W. Smith, of Dublin, remarks, "that difficulties attend the treatment of this fracture may be inferred from the variety of modes which have been proposed to counteract the peculiar deformity which occurs when the lower end of the radius is broken."

Bryant, of Guy's Hospital, asserts that "the wrist-joint rarely recovers its normal movement after this form of fracture, some deformity permanently remaining, of which the patient should be forewarned."

J. R. Barton said: "I do not know any subject on which I have been more frequently consulted than on deformities, rigid joints, inflexible fingers, loss of pronating and supinating motions, and on neuralgic complications resulting from injuries of the wrist and of the carpal extremity of the forearm, one or more of these evils having been left, not merely as a temporary inconvenience but as a permanent consquence." He also speaks of "the embarrassment which every practitioner has experienced in his attempts to obviate eventual deformity and to preserve the functions of the fingers and to restore the motions of the wrist and forearm."

Mr. Callender, of St. Bartholomew's Hospital, in an article on fractures injuring joints, alluding to the unsatisfactory results of such injuries, remarks that, "such results are frequently referred, in some measure at least, to the treatment which has been adopted, but it will not be difficult to show that a great number of these hurts must have a comparatively unfavorable issue, however good the management which is bestowed upon them; still there remain many cases in which the recovery is not so good as it might have been, if only the original injury had been properly determined, and the right plan of treating it properly carried out. From either of these considerations, no fractures, perhaps, require more careful examination than those of the carpal extremity of the radius, for neither is their precise nature clearly defined, nor yet are their unsatisfactory

after-consequences sufficiently, as a rule, impressed upon patients." The same authority states that there are in the museums connected with the London medical schools thirty-six specimens of various fractures of the lower end of the radius, all of which are, if united at all, more or less badly joined together.

The form of fracture which is so liable to occur at the lower end of the radius, and which has such marked characteristics, has been somewhat differently located by various surgical authorities. Colles, of Dublin, who is entitled to the credit of being the first to intelligently describe the injury, locates it at an inch and a half above the carpal articulation. Hamilton describes such fractures as varying in location from half an inch to an inch and a half above the articular surface. R. W. Smith, of Dublin, locates the fracture between one-quarter of an inch and an inch above the joint, and makes a remark, which my own experience will endorse, that it always appears to be higher than it really is. Dupuytren's observations fix the fracture even nearer to the joint, as from three to six lines.

Malgaigne remarks correctly that there may be slight variations in such estimates in accordance with the age and stature of the subjects, which influence the length of the bone, and also from some crushing of the lower fragment by the force of impact. He also notices that there will be variation in the appreciation of the exact position of the fracture, in accordance with the manner of measuring, as owing to the obliquity of the articular surface, the measurement upward from the styloid process, the distance may be one inch, whilst if measured on the inner side it may be but one-third of an inch, and if estimated on the back of the bone about twice the latter distance. The general understanding, however, of such measurment on the living subject has probably been estimated on the back of the articular edge of the bone, which is in the recent injury usually so tilted up as to be quite apparent. Prof. Gross gives it as his opinion that the injury is generally situated low down, within a short distance of, if not actually within, the joint, but is sometimes as high as an inch or an inch and a half above the articulation. Sir Astley Cooper locates the fracture at an inch above the styloid process. Nelaton's opinion is that in the immense majority of cases the bone is broken two-fifths of an inch from the end. Mr. Erichsen fixes it at half an inch.

With reference to the position of the fracture as described by the late Dr. John Rhea Barton, it will be noticed that he merely described, on hypothetical grounds, a fracture of the posterior articular edge of the bone, in which, as he expresses it, "a quite small fragment is broken from the end of the radius on its dorsal side," and is carried upward and backward with the consequently displaced carpus.

Practical experience of careful observers has not, I think, confirmed the observations of Barton. I have never been able to diagnose such a fracture with its accompanying displacement in the living subject, nor have I found it possible to produce it by any kind of violence that I could use on the cadaver. In this view I accord with Hamilton, who states that the fracture as described by Barton, has never come under his observation; and he believes that the description of the injury, which has so generally associated the name of the observer with fracture of the lower end of the radius is incorrect, and that Barton mistook for it the ordinary transverse fracture near to the articular surface of the radius, or possibly a fracture of its styloid process alone. After a number of experiments on the cadaver, with force variously applied, I have not been able to produce the line of fracture described by Barton.

In this country it seems to be the habit of surgeons to incorrectly associate the name of Barton with the usual and very characteristic fracture of the lower end of the radius, an association that cannot be properly made. I am inclined to believe that the only form of fracture that he attempted to describe is one which for want of later surgical and pathological authentication remains as but ideal or mythical, and is not entitled to a separate recognition. If the name of Colles is not used to indicate the injury as ordinarily seen, it should be simply designated by its location as *fracture of the carpal extremity of the radius.*

I am convinced from my own observations upon the subject, which have been carefully made, that fracture of the lower end of the radius, which is attended with such peculiar deformity, and with which every surgeon is familiar, is almost invariably located between a quarter and three-quarters of an inch above the articular surface of the bone.

One of the reasons why the bone breaks so generally within a short distance of its lower extremity, may be found in the fact that its texture at that portion is almost wholly of cancellated tissue, the compact tissue nearly disappearing within three-fourths of an inch from the articular surface. Another cause of weakness is the loss of its cylindrical form, which best resists external force, and is spread into a triangular shape. The force which usually breaks the lower portion of the radius is ordinarily from falls, and is received on the upper part of the palm of the extremely extended hand, in a direction more or less from before backward. The bone is here curved with the concavity on the palmar surface, and the force is spent on the inside of an arch which inclines to fracture the most readily at the point of its greatest curvature on the highest part of the arch, which is about half an inch above the anterior edge of the articulation. When the body falls violently forward the hand is instinctively projected and receives the impact whilst in a state of extreme extension, and bends backward at the wrist-joint to such a degree that the force is communicated to the radius through the palmar carporadial ligaments in a direction almost transverse to the long axis of the bone. Such force would naturally incline to produce fracture in a transverse direction, and I am sure that the usual fracture is ordinarily so effected, rather than, as is generally asserted, by force applied in the long axis of the radius. I am inclined to the opinion that any force violently extending the wrist extremely backward is liable to produce the ordinary fracture of the lower end of the radius, and I have demonstrated that the fracture may be produced on the cadaver by such extreme and forcible backward extension alone.

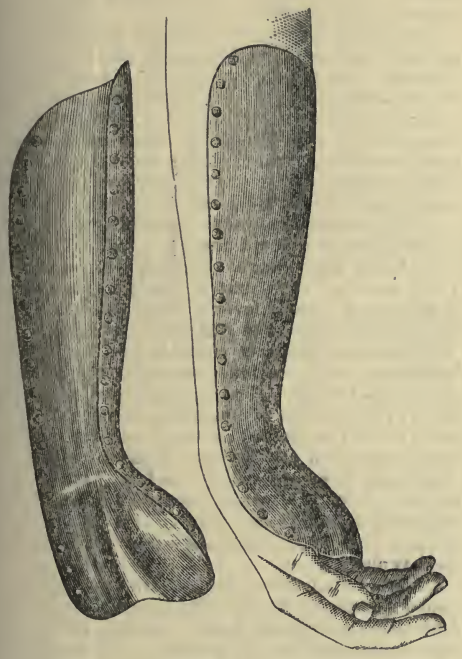
Bouchut asserts, in his observations on luxations of the wrist, that in his efforts to produce dislocations of the radio-carpal articulation in the dead subject, he only succeeded in causing fractures of the lower extremity of the radius. Thus it is shown that an action of simple forcible leverage can cause the peculiar fracture, as well as the more direct impact of force, and may, in frequent instances, be an important factor in the production of the injury. The testimony of nearly all surgeons who have written upon the subject is that in fracture of the lower extremity of the radius the direction of the line of fracture is almost invariably transverse. Examination of by far the greater number of cabinet specimens of the fracture in the museums of this country and of Europe verifies the same observation. The fracture, it is true, is liable to vary in direction and other characteristics with any of the numerous causes which may produce it. Much comminution may occur as in a fall from a great height, when the extremity is thrown forward to protect the body, and I have seen an instance in which the lower end of the radius was much shattered by being crushed under the wheel of a heavy wagon.

Remember then the mechanism of this fracture. It may be described as a simple wrenching of the anterior carpal ligament which is too strong to be torn, hence the bone gives way instead of the ligament. The displacement is an upward and backward one of the lower fragment. The deformity is a depression on the palmar surface, and an elevation on the dorsal surface; this is known as the silver fork deformity. It is usually very characteristic, and was so in the case presented before the resident surgeon reduced the fragment. Displacement of the lower fragment may not exist at all, or it may be to the extent of complete separation from contact of the broken surfaces, varying with the amount of force appplied and with the retaining influence of the surrounding dense structures. The usual treatment of fracture of the lower end of the radius is by what is known as the Bond splint, which is a straight splint with a block on the end for the hand to grasp, and in such a position as to turn the hand slightly to the ulnar side.

I maintain that no crooked bone can be treated on a straight splint. See what the tendency of this splint is: it throws the lower fragment upward, which is exactly what we are trying to overcome. You can obtain good results with this splint if you will place a firm pad of lint or cotton under the end of the upper fragment to correspond with the curve of the radius, and a pad on the dorsal surface over the lower fragment. But the trouble in this is the pad becomes displaced, and slips forward, and throws the lower fragment upwards. You can always tell at a glance the deformities that follow the fracture of the lower end of the radius treated on a straight splint and fractures not properly reduced. The palmar surface is flattened, there is stiffness in the joint, and the hand has a very helpless expression. There is usually neuralgia, from pressure on the nerves, disturbed circulation from pressure on the vessels, and considerable disability of the hand. The first essential in treatment of fracture of the lower end of the radius is the complete reduction of the displacement. The reduction of the fracture can usually be thoroughly effected under anæsthesia, by *strong extension applied to the hand, associated with forced flexion of the wrist, and with pressure applied directly on the dorsal surface of the lower fragment.*

Unless vertical splitting or comminution of the lower fragment exists, the maintaining of partial flexion of the wrist, with pressure of a pad on the dorsal surface of the lower fragment will prevent return of deformity. In the treatment of fracture of the lower end of the radius it is essential that proper allowance be made for the curvature of the anterior or palmar surface of this part of the bone. This is insured in the splint which I have devised, which follows correctly the radial curvature; and the fixing of the thenar and hypothenar eminence of the hand in their moulded beds, maintains the splint immovably in its correct position with reference to the radial curve. To neglect of complete primary reduction of the displacement of the lower fragment, and to inefficient restoration and retention of the normal radial curve, are due the frequent unfortunate sequences of this fracture. This patient was treated by replacement of the fragments by the manœuvres described, and his arm put upon this moulded splint of metal. The splint is made of copper, so as to be readily conformable by bending to suit the peculiarities of size and form of forearms. The series of little pointed elevations along the edge is for the purpose of keeping the bandage from slipping. It is tinned to prevent oxidation. The splint will usually fit the forearm so accurately that but little padding will be

required, and a piece of lint, or of cotton or woolen flannel is all that is necessary for its lining. No dorsal splint is needed, but, as before



mentioned, a small pad will, in most cases, be required over the dorsal surface of the lower fragment. For retention of the splint, an ordinary bandage, two inches and a half to three inches wide, is all that is necessary. This man was dressed by Dr. Barber. I will remove the dressing and see if it has been properly reduced. I see that the deformity is overcome. I now feel that the arch of the radius is perfect, which is the test of the proper reduction. The splint will now be re-applied, and this man can go about and attend to his business. One of the advantages of this treatment is that the patients can attend to their business without much inconvenience. I have had such cases in private practice; one, a bookkeeper, continued writing; another, a bicycler, who took a "header" and produced this fracture, went on with his riding after the fracture was dressed; and also sewing-women who could continue their occupation with very little difficulty. This fracture is very common. I came into this hospital one slippery morning and found six large, stout women sitting in a row, suffering from fracture of the lower end of the radius. They had fallen upon the ice and sustained this injury, which is, probably, the most frequent of all fractures.

Anal Fistule.

This woman is suffering from an anal fistule. An anal fistule is a fistulous tract in the ischio-rectal space, which is the space situated between the rectum and the tuberosity of the ischium, and is filled with adipose tissue. An anal fistule is always the result of an abscess situated in this space, which has opened through the skin or into the rectum, or perhaps in both directions. When a fistule has two openings, one external and the other in the bowel, it is called a complete fistule. When there is an external opening, but no internal one, it is called a blind external fistule. When there is an internal opening, but no external, it is called a blind internal fistule. This distinction is unimportant, because a fistulous tract of long-standing has usually both openings. Blind internal fistules rarely exist; I do not remember ever to have seen one. The error in supposing that external fistules have no internal orifice is due to the fact that the internal opening is not sought for in the right place. It is looked for too high up in the rectum; it is universally situated just above the external sphincter, where your finger will feel a little depression. I pass this probe into the external opening, and you see that it emerges inside just above the sphincter. I now pass a grooved director along the same tract, and with my finger bring the end out at the anus. With a scalpel or bistoury passed along the groove, I cut through the sphincter and other tissues, and thus convert the fistule into an open wound, thus liberating the director. The operation is simply to divide the tissues between the external and internal openings. This woman has also an anal fissure, which is a chronic linear ulcer in one of the folds of mucous membrane, kept open by the continuous action of the sphincter muscle. Anal fissures are curable by putting the parts at rest and then allowing cicatrization to take place. This can be done by stretching or dilating the sphincter with my thumbs in the rectum. This procedure causes slight laceration of the mucous membrane at the seat of ulcer, and paralyzes the sphincter so that granulation will follow and the ulcer become healed. Anal fissure gives excruciating pain *after* the passage of a stool, because of the spasmodic contractions of the sphincter. Hence, you can nearly always make a diagnosis of anal fissure by this occurrence of severe pain *after* defecation.

Having now laid open the fistule, I pack it with a tent soaked in carbolized oil. Having stretched the sphincter and scraped the fissure with my finger nail to get a new surface upon the ulcer, I shall expect the symptoms of anal fissure to disappear.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Discussion on Typhoid Fever. (*See pages* 101 and 132.)

Reported by G. Betton Massey, M. D.

Dr. J. C. Wilson, in opening the discussion, said: "The paper of Dr. Hollopeter is very interesting and suggestive. It touches upon or suggests almost every important clinical problem relating to this disease. Its free discussion would be impossible in one, or indeed in many evenings. Two or three points call for special consideration:

"First. The typical temperature curve, and its variations. The well-known course laid down by Wunderlich as a standard, is met with perhaps less frequently than strongly-marked variations. Nevertheless, a knowlege of that course is the key to the understanding of the variations from it.

Wunderlich, after describing the course of the first four or five days, lays down the law that every case which does not conform to this temperature type is not typhoid fever. This dictum has been the source of manifold errors in diagnosis. No more fallacious statement could be made. Cases of undoubted typhoid fever constantly occur, in which the range of temperature fails to conform to the typical curve, not only in the beginning of the attack but throughout the whole course of the disease. In fact, cases sometimes occur the nature of which is fully established by the complexus of symptoms and the existence of local epidemics, in which the temperature remains throughout even *sub-febrile*. The singularly labile temperature in this disease, rising and falling, as it does, under very slight disturbing external influences, makes it a matter of surprise, not that the temperature is not always typical, but rather that it ever closely conforms to the type.

"Second. The inversion of the diurnal range, of which Dr. Hollopeter has given two instances, is not common. I have seen cases of it, to which I will briefly refer. I am not aware that any adequate theory of this curious clinical phenomenon has yet been advanced.

"Third; house epidemics. The second part of the paper, which considers the details of this curiously-circumscribed and localized outbreak, is very interesting and important. It is by the study of such house epidemics, that a true insight into the etiology of the disease is to be gained. I do not agree with the author of the paper, in ascribing the disease in the infected house to the percolation of waste-water, through the cellar-wall, from the adjoining premises. In order to establish this theory, it would be necessary to show, first, that such percolation, if capable of producing this disease, had not been going on for an indefinite time prior to the attack; and second, that typhoid fever had existed in the neighbor's house, or at least that the dejecta of typhoid patients had been thrown into the pit from which the drainage into the cellar ran. These facts have not been shown. On the other hand, it appeared clear enough that the first case, the young woman, who had come home sick from another house, had introduced the disease. An investigation of the house and neighborhood from which she came, would doubtless shed light upon the subject. House epidemics are numerous in Philadelphia. Certain houses, however, seem to be the abiding place of the infecting principle, seeing that cases occur in them from time to time during a series of years."

Dr. E. T. Bruen: "I have been very much interested in Dr. Hollopeter's paper, and also in the remarks of Dr. Wilson. I agree particularly with the portions relating to the contagion. Two cases recently seen by me illustrate this: a washerwoman took home the clothes of a typhoid-fever patient. Within a week, her two children drooped and became feverish. They were taken to the Children's Hospital and one died there with no autopsy; the other was taken home, where it died, and I made a post-mortem examination. The typical conditions were present. No other cause was known.

"I am also interested in what Dr. Wilson has said about alterations of temperature from slight causes. We notice the same thing in diseases of the liver, in which cases the thermal wave fluctuates with the ingestion of food. If we admit these causes, I think we can readily admit psychic influences in the same role.

"In diagnosing typhoid fever, it is to be distinguished from malarial fever and catarrhal fever. Malarial fever is *sui generis*, and can be controlled in this latitude by quinine. I believe that malaria will modify the initial stages of typhoid fever. Thus one of the groups of cases called typho-malarial takes its name. Neglected malarial fevers form another group of so-called typho-malarial fever, which is not a disease *sui generis*.

"I have seen many cases of mild typhoid fever —the so-called typhoid ambulatorius. Throughout, these cases have shown a temperature of 100°, not over 100°, but I would not make the diagnosis of typhoid fever if the temperature after the fifth day fell below 100° in the evening.

"Catarrhal fever is characterized by peculiar weakness, with various catarrhal conditions of lungs and bowels. The temperature runs from 99° to 100°, and is at times almost normal. Such cases should be classed as catarrhal fever, and are very similar to the specific forms of influenza. They may be recognized by the fact that the temperature is very irregular, and it is impossible to control this feature by quinine. I think these are the cases which have often been confused with mild typhoid."

Dr. Baldwin: "Dr. Levick sometime ago published a paper in which he spoke of a family predisposition to typhoid fever, as well marked in some families as that of phthisis. I should like to ask Dr. Wilson if he has noticed any cases of like character."

Dr. B. Trautmann: "Niemeyer speaks of inverse temperature in typhoid fever, and says that these cases end, generally, fatally. This seems to disagree with the statements made here to-night. I have at this time a case showing this curve, in which a hemorrhage of the bowels followed this morning."

Dr. Kevin: "I have also a case now under treatment showing inverse temperature."

Dr. Arthur V. Meigs: "With regard to the etiology, I do not think Dr. Wilson's position is well taken. In the face of the authority of Murchison, that typhoid fever may arise *de novo*, it seems to me hardly fair to assume the germ theory as proved, although the medical mind seems at present to be inclined in that direction. Typho-malarial fever has always seemed to me a bad name, for it misleads; it means, in its proper sense, a hybrid, both malarial disease and typhoid fever co-existing in the body at the same time."

Dr. W. A. Edwards: "In the case of the young man under my care whose temperature presented the peculiarities spoken of, a diagnosis of double quotidian was made. On the eighth day, signs of typhoid fever set in, and lasted four weeks; then again there was a typical double quotidian. If the case had not been so diagnosed, it would have been put down as a case of typhoid fever with inverted temperature. This, with other cases, I published in the Medical and Surgical Reporter, November 17 and 24, 1883, and mention it to-night to call attention to the fact that all cases of inverted temperature in typhoid fever

are not due to the typhoid entirely, but frequently to a complication, this complication occasionally being almost unrecognizable except for its effect on the temperature."

Dr. Wilson: "A clear comprehension of the mode in which typhoid fever is propagated from previous cases, by means of a specific infecting principle, is of the utmost importance. Murchison, it is true, held that it might arise *de novo*. Nothing in the literature of the subject is more brilliant than that great author's advocacy of this view, but the student of the subject knows that it was asserted in Murchison's day, with a vigor scarcely inferior to that with which it has been defended here, with more success. To Dr. Wilson Budd, of Bristol, is due the credit of showing that Murchison's view was untenable. To-day it is no longer entertained."

Dr. Meigs: "I did not pretend to deny that a single case of typhoid fever may be the focus from which any number of others may arise. I merely contended that in the face of Murchison's opinion that the disease may arise *de novo*, we should be careful how we assume as proved the germ theory."

Dr. J. Solis Cohen: "I do not rise to speak directly to the subject of the paper, as I do not see typhoid fever except in hospital practice. Many years' observation has convinced me that sudden rises of temperature in typhoid fever, as in other diseases, are often due to obstruction of the bowels, even though diarrhœa may exist. A small dose of castor oil will usually quickly relieve the bowels and reduce the temperature. The ordinary milk diet is then to be modified by the addition of lime-water, or by substituting boiled milk for cold. My residents have for years had general instructions to pursue this plan without awaiting my daily visits.

"The family epidemic recorded, reminds me of a similar one in a German family, the members of which were distributed to several hospitals, three of them coming under my own care. A marked local epidemic occurred among the sailors on board the Russian war vessels which, several years ago, were lying off the wharf at Kensington, some sixty of whom came under my care, with the most typical demonstration of the true typhoid curves that I have ever seen. The temperature charts looked as though they might have been copied from a text-book. The cause, in these instances, was the drinking of water from the Delaware river, which the sailors, following an old custom, dipped from the side of the vessel to within a few feet of the open outlets of sewers.

"I was very much interested in the story of the poor washerwoman's family. Our duty, in the presence of contagious disease, is very clear, and is too much neglected by physicians. We should not allow our patients to send clothes out to be washed until they have been thoroughly disinfected. Indeed, rather than subject a family to contagion, let the clothes be burned. Many a poor washerwoman in this city brings typhoid fever, diphtheria, and other diseases, to her household, through the carelessness or indifference of her customers."

Dr. Hollopeter, in closing the discussion, said: I had felt a certain uneasiness in presenting my cases of *inverse temperature*, as I could obtain but little authority for the same, yet I have recorded the simple facts, and am glad to learn that other members have also noticed similar cases. In a future paper I hope to give more of the literature of the subject. In answer to Dr. Wilson, as to the causation of the house epidemic, I would state that Mary, the first to take sick, was, at the time, not living at home, yet she frequently came home for a few days at a time. The family she was working in were all healthy.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

At the meeting November 5, 1884, Dr. H. C. Wood made some

Remarks upon Chronic Contracted Kidney with Normal Urine, Including Acute Gouty Dementia, with a Perforating Recto-vaginal Ulcer, and Death from Sudden Pulmonic Œdema,

Saying: Mrs. L., whose case forms the basis of the present article, was a very intelligent lady, about forty years of age, the mother of five children, of gouty ancestry. At regular intervals of four years she was accustomed to have very violent acute attacks of gout or rheumatism, associated with great systemic disturbance and depression of spirits. As the last gouty sickness was in the early spring of 1880, she was in the spring of the present year in great fear of another attack, and an attempt was made under the direction of her medical adviser, Dr. Tomlinson, to ward off such sickness by careful diet and free horseback exercise. For the early notes of her case, I am indebted to Dr. Tomlinson. An exposure to cold during the night of April 20, was followed by severe coryza, vague pains, and great hebetude, with a very pronounced desire to sleep. Even when moving about she seemed unable to keep her eyes open. Under treatment she improved temporarily. Dr. Tomlinson writes concerning this period: "I could discover nothing wrong with the urine, which she passed in usual quantity. A week later she began to have difficulty in expressing herself; she would use irrelevant words and then correct herself; her gait also grew uncertain, and in walking she would pitch forward as though she were going to fall. April 28, Mrs. L.'s mother died; Mrs. L. was greatly shocked, and rapidly became worse; she was greatly depressed, lachrymose, hysterical, had hallucinations, and ceased to recognize those around her. She lost her appetite, and became constipated. The uncertainty of movement now affected the arms, and there was great failure of memory. Her symptoms continually deepened, the speech became more and more incoherent, until it was a confused senseless jargon. She now refused food, and finally staid in bed in a state of perpetual stupor. The tongue was heavily coated, the breath very offensive. There was no elevation of temperature, or pains, or local soreness."

I was first called to see Mrs. L. May 8; I found her in bed in a sort of stupor, out of which she was with difficulty wakened at all. Getting her partially aroused, I ordered the nurse to put on a wrapper; then commanding and leading the patient, succeeded in getting her to the head of the stairs, then down stairs. It was necessary to

hold her very forcibly, as every few minutes her knees would seem to give way, and she would "flop" to the floor. All this time she said nothing other than incoherent protestations. When she finally was in the parlor I upbraided her loudly and severely for her dishabille and general appearance. On asking her if she was not ashamed of herself, she said she was, and that she had better go up stairs and change her clothes. On my acquiescing, she stood up, and taking the hand of her nurse, walked upstairs, dressed herself with assistance, and came down, recognizing people, but saying very little. I left her eating her breakfast. Her urine was examined at this time; it was loaded with uric acid and urates, although she had been eating very little, had a specific gravity of 1024, and contained no tube-casts, and not the faintest trace of albumen.

She came to the city May 11. She was now completely demented, knowing no one and not recognizing in any way her surroundings. The pupils were contracted and immobile. She ate no food except milk, which was forcibly given her at regular intervals. Much of the time she lay in a stupor in bed; then she would have spells of wandering restlessness; again, distinct maniacal outbreaks, accompanied by violence and indecent speech, or sometimes attacks of muttering delirium. The tongue was brown, dry, coated to the last degree. The teeth were loaded with sordes; the breath horribly offensive; the bowels were obstinately constipated. She was treated with purgatives, quinine, chloral, and morphine when excited.

During these days there was general tenderness, so that whenever she was taken hold of roughly she would scream out, even rousing from a stupor. There was also on movement distinct pain not located in the joints, but seemingly in the muscles. There were very bad hemorrhoids, and at times the patient lay stupid but moaning, with knees drawn up as though there was abdominal pain. The pulse was quick, never much under a hundred, small and feeble rather than strong. Her mental condition grew worse, she took no note of anything, had to be catheterized, etc.

By May 16, the general tenderness had become very pronounced; the pupils were dilated and movable; the intelligence somewhat improved, in that she began to take notice. Salicylates and digitalis were at this time being used freely. On 17th, severe diarrhœa with involuntary passages set in; also the pulse altered suddenly its character, becoming excessively irregular, from 110 to 150 per minute, with beats of all sizes and rates, and many complete intermissions. General tenderness very marked. Auscultation of the heart showed the first sound very weak over the right base; at the left apex the first sound was very weak, the second decidedly accentuated. Over the middle cardiac region the sounds were singularly confused, with a peculiar watery and occasionally grating sound, "believed to be cardiac friction, but no clear positive to-and-fro friction rale." [Note at the time.] A blister was applied over the head and one over the heart.

May 18, menstruation had been established; the pulse had become perfectly regular, 100, and the peculiar middle cardiac sound less distinct. Her mental condition so far improved that she indicated when she desired to pass water, but she could not give a coherent answer to the simplest question.

On the 20th, she, when roused, answered simple questions with some rationality. Severe diarahœa again manifested itself, with involuntary passages, and lasted many days, indeed, off and on, almost to the end; remedies simply kept it in check. There were no maniacal outbreaks, and a slow but progressive improvement in her mental condition began very distinctly directly after the violent diarrhœa of the 20th. The first change was in the recognition of her husband; then when she had a desire to stool; she would insist on getting out of bed to the commode, although she never said why she got up. Then she resisted food and medicine, clearly because she had a will not to have them. On the morning of the 20th she took food herself, knew where she was, and wondered greatly as to the way in which she had got there, having no memory of past events.

June 23 it was first noticed that something was wrong with the vaginal discharge, but a vaginal examination failed to detect any abnormality. On the morning of June 25, fæces were plainly passed per vaginam, and there was discovered a perforation of the recto-vaginal wall very low down, sufficiently large to admit easily the whole forefinger into the rectum. The edges were soft and not well defined. There was no hemorrhage, local swelling, or pain during the formation of this opening, and it was not distinctly sore.

The mental condition of Mrs. L. continued to improve until the first of June. At the same time her tongue cleaned and her breath became sweet. June 1 she was entirely rational, recognized her surroundings and friends, servants, etc., in their proper relations. She spoke very sensibly about her own illness. The memory was very much improved, but by no means normal, and there was an absolute lack of power of mental exertion; but the only thing a casual observer would have noted as peculiar was the character of her voice, which remained very unnatural.

The first indication of a relapse occurred about the first of June, in a renewed coating of the tongue; then she began to talk irrationally at night, and her memory rapidly to fail. Then a tendency to drop or elide words from her sentences came on and was very pronounced. Her talk in the night began to be irrational and incoherent. At times she was quiet during the day, at other times very restless. At night she was very wakeful and restless, getting out of bed, wandering about rooms, etc. Much of the time she had an almost uncontrollable desire to pick at her nose and genitals; some days she refused food, others took it. The pulse ranged from 100 to 120, and her physical strength distinctly increased.

From this time onward her mental state deteriorated rather than ameliorated. She lost power of knowing those about her, although she still recognized her husband; the memory was entirely lost; in a word, she was in a condition of almost complete dementia. July 18th the breathing became suddenly accelerated, and some fine subcrepitant rales were heard posteriorly; on the morning of 18th her breathing grew much worse;

the whole upper lobe of right lung was full of fine crepitation, the left lung also containing rales. This continued for two days with some slight dulness of percussion on left apex, and then gradually subsided. Some days after this she had an equally sudden attack of œdema of the feet. June 24, she was taken about 11 p. m. with violent dyspnœa, accompanied by fine crepitation anteriorly and superiorly in both lungs, and almost complete absence of breath sounds over the posterior lobes. The dyspnœa steadily increased, and she died asphyxiated after twenty-four hours of struggle.

Autopsy.—Kidneys large, plainly in the early stage of chronic interstitial nephritis. Other abdominal organs normal. Heart somewhat hypertrophied; valves normal. Much excess of fluid in pericardium, but no exuded lymph. Lungs highly œdematous; considerable peritoneal as well as pleural serous effusion.

Brain. — Basilar arteries; walls very much thickened, sufficiently so to distinctly interfere with lumen; smaller arteries showing signs of similar endarteritis; the upper and to some extent the basal sub-membranous spaces everywhere distended with exuded fluid; fine vessels of the membrane somewhat congested; a very little lymph in some spots in the membranes. Brain substance very anæmic; the convolutions appeared shrunken; consistence normal, no spots of softening or macroscopic changes to be detected; microscopical examination of the convolutions failed to demonstrate anything abnormal, although the cells were perhaps more granular than normal.

There are certain points about this very remarkable case to which it may be worth while to direct the attention. The cause of the dementia cannot positively be asserted; but I am very strongly inclined to think that it was, at least, in part due to gouty irritation.

It seems to me well established that gout is capable of causing almost every form of insanity; indeed, insanity is only an increase of the mental conditions frequently seen in lithæmia. Carrol in 1859 said, "gouty mania is occasionally seen," and in 1875 Dr. P. Berthier (*Des Nevroses Diathesiques*, Paris,) published a collection of forty-six cases of nervous disease attributable to gout: one, hallucinations; one, migraine; four, tetanus; three, chorea; one, hypochondria; seven, epilepsy; one, paralysis, and twenty-six of mental affection including in these dementia, melancholia with stupor, mania. Although in some of these cases the evidence is not at all positive that gout was the *materies morbi*, yet in others the relation seems to have been clearly made out.

Editorial Department.

Periscope.

The Treatment of Lupus by Erasion or Scraping.

Dr. J. Herbert Stowers having obtained his most satisfactory results from these methods, thus writes about them in the *Brit. Med. Jour.*, Jan. 3, 1885:

The process of erasion advocated by Volkmann is carried out by means of a small hollow and elongated spoon, or scoop, with a moderately sharp edge, set in an ivory or bone handle. The special advantage is, that when the scoop is applied with considerable force, all the diseased tissue, or cell-growth, which is exceedingly vascular and friable, immediately breaks down, and is removed, while the healthy surrounding structures of the skin are too dense and fibrous to be included in the operation.

Those who have had experience of this method, will concur as to the remarkable way the soft, spongy, boggy tissue yields to the scoop, and how much more certainly can the extent and depth of the disease in this manner be estimated. All the cases I have treated thus have have been of long duration, and the new growth in each has existed over an extensive area.

The operation should not be undertaken except with the aid of an anæsthetic, for much of its after success depends upon the complete removal of every tubercle, and, consequently, occupies a considerable period of time. With so vascular a structure also, much hemorrhage results which should be entirely arrested before the solid nitrate of silver is used. I repeat—for it cannot be too carefully noted—that thorough eradication of the abnormal growth must be secured before the scoop is laid aside. In several instances I have operated upon large masses of disease situated over the great vessels of the neck, and, despite the force required, I can truly assert that, with even moderate care, no danger occurs of wounding them.

When the process of scraping is completed, and the hemorrhage arrested (local depletion being, doubtless, an aid to results), the serous discharge escaping from the wounds should be carefully soaked up with clean blotting-paper. Attention to this latter point will obviate the risk of the dissolved caustic running over the surrounding healthy integument, and so adding needlessly to the suffering of the patient.

It is necessary that the nitrate should be pushed deeply into the holes and interstices left by the instrument; in fact, it should be made to burrow into the tissues quite as extensively and deeply.

Considerable inflammation of course follows, which assists ultimate absorption; but the intensity of the pain does not last nearly so long as that attending the use of other caustics.

The parts should be dressed with lint well saturated with carbolized oil; the next day more oil being allowed to run under the dressing. The

second day after the operation, when suppuration has commenced, fresh carbolized oil-dressings should be applied, and so on daily. So severe is the smarting if water be used, that it is preferable, until the discharge is considerable, to cleanse the part by gently rubbing with lint dipped in olive oil, to which a drop or two of carbolic acid may be added. Later, when the sloughs are separating, a weak carbolic acid lotion is advisable for the same purpose, and may with advantage be used with a syringe.

In the cases under my care, which have been, so far, attended with permanently good results, it was necessary to repeat the operation at intervals varying from six to eighteen months; indeed, in some, several repetitions have been compulsory. But I contend, and that very strongly, that, if every new tubercle be immediately attacked, the instances will be few and far between, if any, in which, with the addition of appropriate internal constitutional treatment, the tendency to new development will not be outmatched.

The destructive results of this rebellious affection are too well known to require a word more in this direction; suffice it to say that, in five cases, at least, I have secured noses marked now with a relatively limited scarring, which would otherwise (if left without local treatment) have broken down by extending disease and secondary ulceration, to the production of irremediable and hideous deformities.

The natural tendency to recur must never be accepted as sufficient reason for not contending again and again with the disease until that age or condition of health be reached which will secure lasting and permanent immunity.

I would recommend, not less strongly, that any neighboring tissue, while suspicious in character, though not readily breaking down under the scoop, should be freely submitted to multiple punctiform or linear scarification, combined with a liberal use of the solid nitrate of silver.

Three cases alone, taken from my note-book, will suffice to illustrate practically the value of the above treatment, and with these I conclude:

Case 1. Emily D., aged 20 in July, 1883. Extensive lupus of nose. Residing at Chislehurst. Duration eight years. Four operations under ether: one in 1881; two in 1882; one in 1883 (February). No return up to present date. Cicatrices well formed and healthy.

Case 2. Anne K., aged 27 in 1877. Residing in Bedfordshire. Extensive lupus of cheek. Duration twenty years. Two operations under ether: one in January, 1881; one in 1882. No return up to present date. Parts look quite healthy.

Case 3. Elizabeth C., aged 19 in 1880. Lupus of nose. Duration nine years. Three operations during 1880 and 1881. Perfect scar-tissue now remaining. No evidence of disease returning.

Nerve-stretching for Sciatica.

Dr. A. B. Atherton gives the following instructive case in the *Canadian Practitioner:*

1882, September 8. G. E. G., aged 40, male, minister, not generally very robust. One or two members of family have had phthisis. Seven years ago suffered for several months from sciatica in left limb. Also four years ago had an attack of pneumonia or pleurisy, or both, which laid him up six or seven weeks. Eighteen months ago sciatica returned, and in spite of all sorts of remedies, it has grown worse, till of late it has interfered very materially with his ministerial duties. Morphine relieves the pain of severe paroxysms, but it causes so much nausea and vomiting that he dreads its use. Rest relieves, and motion increases, the pain and soreness. As a rule he is able to sleep pretty well at night, but he is wakened when he attempts to turn in bed. He has lost more than twenty pounds of flesh, weighing now less than 120. When a paroxysm of pain occurs, he is often troubled in passing water. Pain is most severe at point of exit of nerve through greater ischiatic foramen, radiating from this upwards over side of pelvis and down thigh. Also often feels pain in calf of leg and foot, accompanied with numbness and coldness of part. Has worn, of late, a chamois skin on the left limb to protect it from the cold. Has used cane in walking for some months, and leans considerably to right side when doing so. Has been troubled very much with dyspeptic symptoms since his illness.

On examination there is found considerable wasting of limb in its whole extent, the calf and thigh measuring one-third of an inch less than their fellows. Also muscles are soft and flabby. Tenderness complained of along line of upper part of nerve. Bowels always regular.

3 p. m. Operation. Chloroform given. Incision made from over lower border of gluteus maximus downwards, and a little inwards, four inches in length. The long head of the biceps was thus brought into view, and on turning this aside the sciatic nerve was reached. I now hooked my finger beneath the latter, and gave it two or three vigorous pulls from both above and below. There was a sensible yielding of the nerve in its lower part, but little or none in the upper.

Carbolic acid and alcohol (1 to 10) now applied freely to raw surfaces, and horse-hair put in for drainage. Silver and catgut sutures used and carbolized gauze and salicylic silk applied as a dressing.

September 9. Slept several hours last night without opiate. Feels very little pain, and he thinks he can move more easily than before operation. Pulse 88; temperature 99.8°.

September 11. Doing well. Appetite good. Pulse 80; temperature normal. Dressing changed under carbolic spray this afternoon. Horse-hair removed from wound. Only a slight bloody discharge on gauze.

September 12. Expresses 'himself as 'more free from pain than for a year past. Bowels have moved regularly since operation. Pulse 76; temperature 98°.

September 15. Doing well. Pulse and temperature normal. Wound again dressed. All sutures removed but three. Wound about healed. Adhesive plaster and dry dressing.

September 17. Remaining sutures removed. Wound healed. May get up and dress and lie on couch during day.

September 19. Since getting up, he feels some soreness all along back of limb, as if a "cord had been strained." Walks about, however, with the aid of a cane, and feels little, if any, of old pains.

October 9. Some soreness complained of still along course of nerve, but otherwise is doing well. Has gained six or eight pounds since operation, and walks much more erectly than before.

October 25. Returned home to Annapolis, Nova Scotia, to-day. Soreness along line of nerve is nearly all gone.

1883, May 6. Patient called to see me while on a visit to Fredericton. Has no appreciable halt now in his gait. Weighs 135 pounds. Says that he occasionally feels slight pain over left ilium, but does not mind it. Limb is now same size as the right.

Koch on the Comma-Bacillus.

The *London Med. Record* tells us that Dr. Koch has lately published a critique of the latest opinions on the comma-bacillus, in the *Deutsche Med. Wochensch.*, No. 45. In the first place, Koch especially insists, as on previous occasions, that our opinion about any particular kinds of bacteria must not rest upon one-sided observation of certain morphological characters only, but must be formed from the consideration of their whole properties, biological as well as morphological. A particular species of bacteria is only characterized as such by the sum-total of its properties, and it can be diagnosed only with reference to its whole behavior. Our investigations should be undertaken with the full consciousness of the indispensable necessity of this postulate, and under the absolute guidance of the methods employed, if we venture on the difficult question of the relationship of the comma-bacilli. Unfortunately, this cannot be said of investigators so far. It may be remembered, from the reports of the Natural Science meeting at Magdeburg, that Dr. Klamann alleged that he had found in cholera nostras similar bacilli and spirilla to those of Finkler and Prior. Klamann sent preparations, partly from dejections, partly from cultivations, to Koch, and neither this investigator nor other microscopists have been able to find anything like curved bacilli or spirilla in them.

The so-called comma-bacilli found by Lewis in the saliva, and long known to Koch, are longer, slenderer, and more pointed at the ends than the cholera-bacilli, and, when not too deeply stained, appear less dark at the ends than in the middle. But more important than the morphological differences are the biological. For, unlike the cholera-bacilli, these bacilli of the saliva do not develop in neutral or weakly alkaline cultivation-fluids, and the distinction between the two kinds is thus easily made.

Drs. Finkler and Prior are reproached with having entered on their difficult problem with insufficient knowledge and preparation. The fact that their cultivations were made on potatoes or on moist linen instead of on gelatine, deprived them of the particular advantage of the latter method, viz., an assured separation of the different varieties by successive cultivations; for one individual bacterium cannot be thus dealt with, but only a majority of different bacteria. The potato-culture affords no protection against the predominance of other kinds, which thrive very well by this method. Later impurities may also have occurred, and there is no guarantee that the ultimate appearances are due to the original inoculation.

Moreover, the ideas of Drs. Finkler and Prior on bacterial spores are diametrically opposed to our knowledge of bacteriology, because they regard the stained ends of the bacillus as spores, instead of looking for them in the unstained middle portion. On these and the above grounds, their assumptions regarding further conditions of development are devoid of a firm basis.

A cultivation sent to Koch by the above observers as "pretty pure," and obtained from "decomposed dejecta," showed four different kinds of bacilli on cultivation in gelatine. Of these, the individuals of one kind only were slightly curved or citron-shaped. On drying and staining, they presented a certain resemblance to comma-bacilli, but were on the whole plumper and larger, and developed more energetically both in gelatine and in potatoes. The separate colonies in gelatine were of an uniformly round shape under a low magnifying power, presented a finely granular appearance, and quickly fluidified the gelatine for a good distance round. The colonies formed by "cholera-bacilli," on the other hand, are not uniformly round, but have a zigzag periphery, are bright in appearance, of a long funnel-shape, and do not fluidify the gelatine like other bacteria. Similar differences are found in cultivation experiments in test-tubes. On potatoes, the bacteria of Finkler and Prior developed rapidly at a temperature of between 17° and 19° C., forming a pale yellowish-grey mucous mass, and the potato appeared white at the periphery of this. "Cholera-bacteria" do not grow in potatoes at this temperature, but only in a proper apparatus, where they slowly develop to dark-brown colonies.

Koch is in doubt as to whether the above bacteria originated in the intestine, and not rather in the decomposing dejecta and fluids after death. In preparations from fresh dejections only the ordinary bacteria were found, but no comma-bacilli.

Three cases of cholera nostras (two of which were fatal) and one case of arsenic poisoning (which succumbed on the tenth day) were most carefully examined by Koch, but with negative results. Moreover, hundreds of separate observations, recently made at the Sanitary Institute of Berlin on dejections from healthy and diseased persons, saliva, and buccal mucus, have never afforded the true "comma-bacillus."

Comma-bacilli, says Koch, are specific bacteria, belonging exclusively to cholera Asiatica.

In connection with the experiments of Rietsch and Nicati (vide *Berliner Klin. Woch.*, No. 35) a very diluted pure culture—hardly the hundredth of a drop of the culture fluid was used—was injected into the duodenum, without tying the ductus choledochus. With few exceptions, the animals died after a day and a half to three days. The mucous membrane of the intestine was reddened; the contents were watery, colorless, or slightly reddened, and at the same time flocculent. The comma-bacilli were found in the intestinal contents in a pure culture, and in extraordinary quantity. In other words, the same appearances existed as after fresh cholera. A simultaneous intoxication from poisonous products, which might be present in the culture fluid used for injection, is excluded by the smallness of the quantity taken.

The Action of Disinfectants on Carbuncle.

Professor Perroncito (*Annali Univ. di Med.*, July, 1884), examining the best means for disinfection for cattle-trucks, especially with regard to carbuncle, recommended in 1881 a 5 per cent. solution of sulphurous acid. To this the railway authorities objected, as it was found to damage their property, and further experience showed that, while it destroyed the virulence of the bacilli, the spores were unaffected. Hot water, chlorine, sulphurous acid, and hyponitric acid gases were tried, but were given up as expensive, inconvenient, or inefficacious. Professor Perroncito then made a series of careful experiments to determine the best and most active disinfectant, especially with regard to the bacillus and spores of bacillus anthracis. He found the following results:

1. Solutions of from 5, 10, or 20 per cent. of chloride of sodium had no influence on the spores or bacilli, the bacilli even developing spores freely in a 5 to 10 per cent. solution.

2. Solutions of carbolic acid, 1 per cent., destroyed the virulence of the bacilli, while the spores resisted a 10 per cent. solution.

3. Spores resisted a warm saturated solution of salicylic acid, and a 50 per cent. alcoholic solution. The bacilli perished in a cold saturated solution after five minutes.

4. Carbolate of soda, 5.5 per cent., killed the bacilli, but not the spores.

5. A saturated watery or alcoholic solution of thymol killed the bacilli, but not the spores.

6. Chlorine gas, even after seven hours' action, did not give complete disinfection, but chlorine water killed the bacilli in five minutes, and the spores in an hour and a half. The chlorine water must be freshly prepared. The method of Vitali is the best. Three kilogrammes of chloride of lime are mixed with 100 litres of water; six litres of sulphuric acid (1-5 water) are then added. Sulphate of lime is precipitated, and the chlorine formed is dissolved in the water.

7. Bromine destroys the virus liquid better than gas.

8. Sulphurous anhydride kills the bacteria in less than twenty minutes, but after 50 hours' exposure the spores are not hurt.

9. Saturated solution of permanganate of potash does not kill the spores, even after 52 hours' exposure.

10. The spores, after being kept for eight days in a solution of sulphophenate of zinc, retained their virulence.

11. Sulphuric acid, diluted to 1 per cent., added in equal parts to anthrax liquids, destroyed the bacilli in less than 15 minutes, while the spores resisted a 5 per cent. solution for more than seven days, and a 15 per cent. solution for more than 17 hours. The virulence of the spores was neutralized by 5 per cent. solution when in contact with them for 11 days.

12. A 4 per cent. solution of sulphate of iron did not kill the spores in six days, nor did a 20 per cent. solution of sulphate of copper in four days, nor a 4 per cent. solution of sulphate of zinc in 13 days.

13. A 4 per cent. solution of pyrogallic acid left the spores unaltered after six days' contact.

14. Very numerous experiments were made with 1 per cent. and 1 per thousand solutions of corrosive sublimate. Solutions of 2 per cent. killed the spores of bacillus anthracis in less than 20 minutes. Solutions of 4 per thousand killed them in under 35 minutes, and 1 per thousand in about one hour; 2 per thousand in two hours; 1 to 5,000 did not kill them after 10 days' exposure; 1 to 6,000 required 80 to 90 days; and 1 to 10,000 did not kill them after 9 months.

15. Glycerine destroyed the virulence of the bacilli after some days, but the spores resisted more than 14 months, and perhaps indefinitely.

16. Solutions of potash and ammonia and picric acid, even when concentrated, required many days to affect the spores.

17. Bichloride of quinine and glacial acetic acid killed the bacilli in a few minutes, but the spores resisted acetic acid for 87 or more days.

18. Absolute and commercial alcohol killed the bacilli in less than 5 minutes, but the spores, after 120 immersions in absolute alcohol were still virulent.

19. Essence of cloves did not kill the spores even after 20 days' immersion, nor sulphide of carbon after 49 days.

20. A saturated solution of chloride of zinc killed the bacilli in a few minutes, but the spores resisted more than 6 days.

21. Sulphites of soda and magnesia and "pellagrozein" (the poisonous principle of heated maize, which is supposed to cause pellagra by Prof. Lombroso) were not efficacious.

Prof. Perroncito finally recommends fresh chlorine water or super-heated steam as the best disinfectants for anthrax.

Operation for Relief of Strangulated Inguinal Hernia, also for its Radical Cure, in a Child Two Years of Age.

Dr. George Buchanan reports the following case in the *Brit. Med. Jour.*, January 3, 1885:

John M., aged two years and four months, was admitted to the Western Infirmary, Glasgow, on September 25th, at 10 p. m. The history of the case is that, when a few days old, a swelling was observed in the scrotum on the right side, and subsqeuently on the left. These, which could be reduced in size, were believed to be hernia, for which a double truss was worn, but without much effect, as the rupture on the left side repeatedly came down, and the swelling on the right never was completely reduced. This state of affairs was allowed to go on till the day before the child was brought to the hospital, when, after a severe fit of crying, the swelling on the left side of the scrotum suddenly increased, became very tense, and could not be returned. During the night the child suffered much pain, and, in the morning, vomiting occurred. In the afternoon a medical man was called, who endeavored, by careful and continued manipulation, to return the hernia, but without effect.

When the child was taken to the hospital, the house-surgeon, finding vomiting still persisting and the tumor firm and unyielding, sent for me.

I put the child under the influence of chloroform, and again tried taxis, but without avail. I then cut down and relieved the stricture, which

was very tight. The intestine, which was dark purple in color, was returned after gentle pressure. I then drew the pillars of the canal together with three silver wire-sutures, in the way I do when performing the operation for the radical cure in ordinary circumstances. The wound was dressed antiseptically.

There was no hernia on the opposite side, but distinct enlargement of the testicle. Possibly this, with a certain quantity of fluid in the sac, may have been the state of matters throughout.

It is unnecessary to give details of the progress of the case, which terminated by the complete agglutination of the inguinal canal boundaries, and the radical cure of the hernia.

Remarks.—This is the only case, within a hospital-experience of twenty-five years, in which I have had to operate on so young a child. And from a pretty extensive inquiry, I learn that the experience of other surgeons is similar. Some surgeons are under the impression that the operation is almost never imperative. But the experience of one of my colleagues, who operated on a child equally young a few months ago, shows that sometimes in children, equally as in adults, operative procedure is too long delayed. In the case referred to, attempts at taxis had been frequently repeated, before the child was sent to the hospital, and the bowel was found approaching to gangrene, and the result was fatal. But, further, I hold that delay in such cases, or even in those which have resisted very moderate attempts at reduction, is uncalled for and unwise, because advantage may be taken of the child being under chloroform to perform the radical cure; it adds nothing whatever to the danger of the operation, and brings about a most desirable result. Every year's experience convinces me that there are a very great number of children in whom cure by truss is, or at all events has become, totally impracticable. Theoretically, every child with a hernia should be provided with a truss which will keep it up; and every mother ought to be instructed so to manage the truss that the hernia will never be allowed to come down. But, practically, in hundreds of infants, this is impossible.

How Cholera Travels.

Dr Pettenkofer writes in the *Popular Science Monthly:*

The disease is best known in Europe under the names of cholera, cholera morbus, Asiatic cholera, since the epidemic of 1817 to 1819, in which the English army, under the command of the Marquis of Hastings during a war against the natives, was rendered unfit for fighting and almost annihilated. But cholera had never visited Europe till the present century, when in 1830 it appeared in Russia and spread to Poland, where war was prevailing. Since that time, sometimes at longer and sometimes at shorter intervals, cholera has appeared in Europe. The question why cholera remained a thousand years in India before it first began to migrate is one of great interest, but one which cannot be satisfactorily answered. The principal consideration appears to me to be that the event happened at the time when intercommunication in all directions, both by water and land, had become more rapid. The first steamship appeared in the Indian waters at the beginning of the second decade of the present century. By land also intercourse was greatly accelerated. The Russians possibly took cholera from India, Arabia, Afghanistan, or Persia, through couriers and stage-coaches. It soon became clear that cholera, the specific cholera-germ, was in some way or other propagated along the paths of human intercourse, and it also became evident that unless the germs found a suitable soil within a certain time they did not flourish. Observers soon discovered that cholera was more prone to appear in certain regions and to affect certain localities, while it shunned other districts; and, again, that other regions were only visited at intervals of many years. It is also a fact that Asiatic cholera never yet appeared at a place which had not previously been in communication with a region where cholera prevailed; and, further, that the disease from an infected locality never yet passed on to another place if the journey lasted a certain time without interruption. The large intercourse between India and Europe, more particularly England, by means of ships which sailed round the Cape of Good Hope, had never succeeded in carrying cholera from India to England.

Railway Accidents and Color-Blindness.

It has not been the duty of the writer to investigate cases of accident which might have been caused by defects of sight, but he has been assured by officials that a solution will hereafter be found in them for those hitherto insoluble mysteries where men, otherwise credible, have so flatly contradicted themselves and the circumstances of the case. By one prominent officer he was told that, being upon a train at night delayed by some slight accident, he himself took a red lantern, and, going a proper distance back, placed himself on the track in the way of an on-coming train, but, finding his light not observed, he was compelled to dash it into the cab to attract the engineer's attention and arrest him in his progress to a collision. Upon the examination of another engineer, his superior officer being present and convinced of his marked color-blindness, remarked that, but a short time before, the man had run into the rear of a train properly protected by a red light in the hands of a brakeman some distance in the rear, that the most careful investigation had resulted only in the suspension of the brakeman for not having gone far enough back, but that he was now satisfied that the color-blindness of the engineer had been the real cause of the accident. Some slight or minor accidents recently led to the discovery that another engineer had by some oversight not been tested in his division, and this led to his examination and detection there, and to his conviction by the writer as a color-blind. Still another case now presents itself. An engineer some time ago ran over and killed a brakeman holding a danger-signal on the track in front of his engine, and no satisfactory explanation could then be given; but the division examiner predicted that he would probably be found color-blind, and on his examination this proved to be the case.—*From "The Sight and Hearing of Railway Employees," by Dr. William Thomson, in Popular Science Monthly for February.*

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

TREATMENT OF ASIATIC CHOLERA.

During the last cholera-epidemic in Italy, Prof. A. Cantani had the opportunity of treating a large number of cholera patients. He has published the results of his observations in the *Deutsche Med. Zeitung*, December 11, 1884. From this voluminous paper we take but the two following points as specially important.

In every case, where early in the cholera-diarrhœa, within one or two hours after its first appearance, the following injection was carried high up in the bowel, the outbreak of the graver disease was surely prevented, and a few injections invariably sufficed to put an end to the rice-water discharges:

℞.	Infus. flor. chamomillæ,	2 liter.
	Acid. tannic,	3-6 grm.
	Gummi Arabici,	30-50 grm.
	Tinct. opii deodor.,	30-50 drops.

In an orphan asylum most of the older persons had died of cholera when Prof. Pitone arrived, and at once instituted systematic injections of the above fluid. In every case amelioration of the symptoms at once set in, and forty-eight hours later all the patients were out of danger, while according to Pitone's view, they would probably have all shared the fate of those who had died before he came, as so often happened in similar institutions of Naples during the last epidemic.

In the algid stage (of collapse), many a human life has been saved by the intravenous injection of a solution of common cooking salt —chloride of sodium. It is remarkable to note the effect. After a liter has been injected into the vein at the arm, the patient, who already seemed dying, and appeared shrivelled, suddenly changes the expression of his face, the spasms cease, he seems visibly to gain in weight, the pulse at the wrist once more becomes perceptible, the voice loses its peculiar hoarseness, that fearful sensation of anxiety, so characteristic of cholera, and so ominous as announcing approaching dissolution, vanishes, and reaction sets in, thus saving life.

Notwithstanding all theoretical opinions to the contrary, Cantani strongly recommends these intravenous injections, and says that they have not

failed him in a single case, and that he invariably saved the life of the patient, if the latter still evinced symptoms of life while he made the injection. No matter how severe the symptoms of collapse, if the heart's action can still be felt, reaction invariably sets in within from one to two minutes after the injection of the chloride of sodium, which seems at once again to fill up the impoverished vessels with fluid. A whole liter should at once be injected, and the fluid ought to have the bodily temperature. Cantani guarantees an effect as long as paralysis of the heart has not yet set in and power of absorption still continues, no matter how grave otherwise the symptoms may be.

In case the cholera visit us, it may be well to try both kinds of injections, the one in the prodromic diarrhœa, and the other in the final stage of collapse.

DETECTION OF POISON IN SAUSAGES.

Remarkable cases of illness often develop themselves after the swallowing of sausages or other meat finely cut up. We do not refer to the so-called sausage-poison, the exact character of which has first been determined by Virchow, and the cause of which is a septic bacterium, but we mean the common parasite, Finne, which rarely produces death, but cholera-like symptoms, which, though but seldom fatal, are exceedingly annoying to the patient suffering from them.

The parasite, if isolated in water or in some other pure fluid, can be recognized under the microscope with comparative ease, but when present in the contents of the alimentary canal, or when mixed up with the finely-cut meat, its demonstration becomes one of the most difficult labors, and this fact is the reason why the discovery of this parasite has so often escaped the scrutiny of the most experienced microscopists.

Dr. Schmidt, in Mülheim (*Deutsch. Zei.sch. f. Tiermedicin und Vergl. Pathol.*, Bd. x., H. 5 and 6), while making some experiments recently, observed a remarkable tenacity which this parasite evinced against the action of the gastric juice, and further investigations have proved to him that we possess in this fluid the best means for the discovery of the parasite in mixed, finely-cut up meats. He proposes the following method:

A sufficient quantity of the sausage or finely-cut-up meat is digested for several hours by the aid of artificial gastric juice six to eight times of its volume under continuous stirring and at a temperature of 101°F. Thus, meat and fat are digested, the latter accumulating on the surface in the form of a more or less emulsified layer, but only the wall of the vesicle of the parasite is attacked, while the heads, hooks, and hook-wreaths are intact. These parts of the parasite possess a high specific gravity, and they therefore soon collect at the bottom of the vessel in the shape of white round bodies of the size of a rice-kernel. Only after an action of the gastric juice continued for several days can a trace of its having attacked the parasites be detected.

On careful inspection, especially if made under water, as ought to be done, there appears across these white bodies a transverse fissure, and the head of the parasite will be found either withdrawn into its caspule or slightly pushed forward. In either case, the head may be easily isolated by the aid of the needle; and its digestive and other apparatus, if put into glycerine, may be readily distinguished if twenty times magnified.

TREATMENT OF RETRO-UTERINE HEMORRHAGES.

As is well known regarding the treatment of retro-uterine hemorrhages, the doubt still exists, whether laparotomy or the vaginal opening of the blood-tumor merit the preference. Martin represents the views of those who think that by laparotomy they are better able to remove thoroughly all blood-clots from the sac than can be done by elytrotomy (opening per vaginam).

P. Zweifel (*Deutsche Med. Zeitung*, No. 100, 1884, December 15) has recently investigated the subject. He believes that, from a theoretical point of view, the adherents of Martin were right, but that practically the scraping of the sac could be done with the same ease and thoroughness, if performed per vaginam. He recommends

an opening of two or three fingers' width in the vagina, and says, that with a cautious use of the dull curette the danger of hemorrhage need not be apprehended.

In laparotomy, the surgical injury is greater, the operation more complicated, and the transfer of the contents of the tumor into the abdominal cavity scarcely to be avoided. Regarding statistics, the figures thus far still are rather small, but as far as they go they doubtless speak in favor of the operation per vaginam. The cavity can be emptied with the same ease and disinfection of it, as well as any local application of whatever kind may be performed with far greater security, there not being the risk of either the contents of the sac or of the injected fluids entering the peritoneal cavity. Where, therefore, no special reasons, as abnormal position of the implicated parts, contra-indicate the operation the opening of the sac should always be made from the vagina, and laparotomy performed only in specially-selected cases, which do not permit the other method.

HÆMATOCELE, HÆMATOSALPINX, AND THE REFLEX THEORY.

After reporting a number of such cases, some of them observed by himself, Dr. Otto Alberts, in Berlin, endeavors to answer the question, how the blood-tumors of the tubes have their origin (*Deutsche Med. Zeitung*, No. 100, p. 573).

Considering the nature of the affection, there are but three possibilities. Either these tumors are caused by hemorrhages of the mucous membrane of the Fallopian tubes, or they develop themselves in consequence of venous stagnation in the uterus, or both causes act in unison.

The reflex-theory, notwithstanding that experiments on the dead body seem to prove its correctness, is thrown aside by A. The muscular contraction of the living tube is similar to the intestinal peristaltic, and to judge from the locomotion of the ovum, a centrifugal one. But there is no doubt that the tube itself is the cause of the bleeding. Numerous observations have demonstrated that at the time of the menses a physiological hemorrhagic exudation takes place from the mucous membrane of the tubes.

The diagnosis of the hæmatosalpinx is exceedingly difficult, if not discovered on the dead body or determined during life by puncture of the sac. Besides, it usually offers every time a varying picture in the different stages of its development, and neighboring inflammatory processes generally so complicate the affection that but a probable diagnosis can be made in the average case. The treatment best to be recommended would, therefore, be an expectant one, though the results of the post-mortem examinations make us fear that the fatal issue will probably be the general rule, from which rarely an exception may be noted.

Notes and Comments.

Acute Purpura Hæmorrhagica in a Child.

This disease, rare as it is in adults, is so very unusual in young children that the case which Dr. R. A. Gibbons reports in the *London Med. Times*, January 3, 1885, is worthy of note. The patient was a boy aged three years, who had been under treatment for eighteen months, suffering from chronic enteritis. His diet had been carefully regulated during all this chronic illness. His family history was good; syphilis was denied, and there was no reason to suspect it. Physical examination failed to reveal any enlarged glands at any time, and the liver and spleen were not palpable. There was no pus in the dejecta, and the urine never contained albumen. Last July (15) he was seized with an attack of diarrhœa similar to many others he had had during his long illness, and there was occasional epistaxis. He was now found to have extravasations of blood in various parts of the body. Very soon a *bloody* diarrhœa set in, which rapidly increased in severity, defying all remedies to check it. He therefore, had nothing more than small quantities of brandy and meat essence by the mouth. The motions still continued, and were more frequent, at least every fifteen minutes, but were smaller in quantity. The child gradually became blanched to the last degree, the lips and conjunctivæ having lost all color, and he looked like a pale wax model. About 3 a. m., July 16, he suddenly sat up in bed and vomited a perfect stream of apparently pure blood, part of it being blackened. At

least a quart must have been thus ejected, judging from the amount caught in a basin, and the state of the bed-clothes, which were quite saturated. After this, he declared he felt better, and was perfectly conscious, speaking to his mother and the nurse. He was now no longer irritable, nor did he complain of any abdominal pain, which, up to this time, had been constant, whilst his strength had visibly failed, and after being gently lifted on to a clean bed close by, he spoke very little, remaining, however, sensible for about three-quarters of an hour longer, when the pulse, which had been extremely feeble, gradually failed, and he quietly passed away.

The points of special interest about this case are the extremely rapid course, the comparative freedom from epistaxis, and the large amount of blood passed by the rectum, the hæmatemesis, the absence of faintness and convulsions, the latter being so frequent in children dying of copious hemorrhage, and the perfect consciousness up till within a few minutes of death.

Gastrostomy.

A short paper in the *New York Medical Journal* contains some points of interest. At one period in the history of the patient, when a partially dilated œsophageal stricture exhibited a tendency to rapid contraction, a very efficient dilator was improvised by the use of the transparent part of "lemon-candy," which was softened by heat and moulded into the proper shape about the looped extremity of a stout iron wire. These candy dilators were well borne, and the stricture was thus gradually dilated to a calibre of one inch. Dr. Bushnell remarks that an examination of the after-history of patients who have been subjected to gastrostomy when much reduced by starvation, prompts the doubt as to whether any benefit was derived from the subsequent introduction of food into the stomach. Peristalsis is interfered with by the stitches and the broad adhesions; adhesions are a recognized cause of dilatation, and the starved stomach of the gastrostomized must be peculiarly unfitted to overcome such hindrances to its activity; the exposed portion of the viscus becomes inflamed under the influence of the air and of the wound discharge; its circulation is impeded by the stitches (Gross's statistics show four deaths from gangrene of the stomach in 137 gastrostomies), and from the diminution of its muscular contractions; its innervation probably suffers in proportion; and amidst such disturbances, neither the secretion of gastric juice nor the absorption of peptones can be expected to take place normally. There is also danger of the food gravitating into the splenic end of the stomach and remaining there to ferment. It is therefore advised that all food should be thoroughly peptonized before administration; that forty-eight hours after the operation the patient should be placed on his right side after feeding, to favor gravitation towards the pylorus; that hydrochloric acid be added to the food (increased acidity favors the passage of the stomach-contents through the pylorus, *Leube*); that the viscus be frequently washed out by a siphon; that, to spare the stomach, the water needed should be supplied by enemata. (It is noted that the patient referred to, who received a quart of water daily *per rectum*, with chips of ice to suck *ad lib.*, never complained of the thirst which usually adds so much to the sufferings of œsophageal stricture.)

Pent-up Secretions.

Among the more recent contributions to practical medical literature there have been few that compare with the paper on the above subject, which Dr. C. G. Wheelhouse contributes to the *Brit. Med. Jour.*, January 3, 1885. It may be—indeed it sometimes is—that the consequences of pent-up secretions are neither important nor serious; thus, in the case of an over-active tunica vaginalis, beyond the discomfort arising out of the weight and size of the resulting hydrocele, no other evil consequence need be greatly feared.

In some, as in the case of the pleura, it may be that the contained viscus, though essentially vital to life, may permit a certain amount of crowding; and, if not unduly pressed, or for too long a time, may, when the pressure is removed, be restored uninjured to its pristine condition, and no permanent harm may have been done.

Thus, many simple effusions of serum into the pleura doubtless occur, are reabsorbed without causing more than temporary inconvenience, and leave no evident traces of their existence behind them; and, provided relief be obtained through the help afforded either by the physician or the surgeon, the spongy lung, uninjured in texture, will resume its normal position and functions almost as if nothing had happened, and no trace of the effusion may remain.

The writer then goes on to demonstrate how, with antiseptic precautions, pent-up secretions that threaten life can be safely withdrawn by surgical interference from the pleura, the pericardium, the lung, the cavity of the uterus, the brain, liver, kidney, and other important organs.

He strongly says: "When I was young he would have been a bold man who would have ventured, unless in presence of destructive disease, to make a direct and free incision into the knee-joint, whereas now we do so—shall I say with impunity? —well, almost with impunity, and certainly without much fear; but I have known death follow the simple removal of a loose cartilage from the knee-joint, and I have known many limbs amputated through the thigh for injury to the knee-joint, which we should never think of condemning now; and all this is the result of one only of the many great discoveries of our age."

Treatment of Fractured Patella.

The latest apparatus devised to this end is described by Dr. Hobart Burge, in the *New York Medical Journal* for September 6th. The limb rests on a padded straight board, which is divided and hinged opposite to the knee, to provide for slight passive motion, and to which a movable foot-piece is attached; it also carries, on either side of the knee joint, a pair of small brass pulleys, round which cords can be passed to weights depending from the foot of the bed. The splints proper are of sole-leather, one about a foot long, five or six inches broad at its upper end, and narrowed towards the knee and made concave at its lower end so as to fit the upper border of the patella; the other splint about three and a half inches square, and cut out at its upper margin so as to fit the lower border of the bone. The splints are soaked for a few minutes in cold water, until quite pliable, padded on one side with cotton-wool neatly covered with unbleached muslin, and then bound on to the limb with roller bandage as nearly as possible in the position which they are intended to occupy. In a few hours they are thoroughly moulded to the limb, and as firm as board. The roller is then removed, and the middle of a small strong cord is sewn firmly just above the concave margin of each splint, and its ends passed through the pulleys and attached to the weights, so as to approximate the concave margins of the splints, and thus to draw together the fragments of the patella which they embrace. The splints are so firm and fit so accurately that no bandages are necessary; they need only to be tied in place by bands passing, not directly around the limb, but under the board on which the limb rests. The weights may vary from one to three pounds. The apparatus is comfortable, inexpensive, and efficient, while it possesses the advantage of leaving the site of injury constantly exposed for the surgeon's observation.

Treatment of Entropion.

At the last meeting of the French Society of Surgery in Paris, Dr. Terrier reported that Viensse, a military surgeon in Algiers, saw an Arab who had been treated for an entropion by an Arabian physician with the ferrum candens (actual cautery). It was remarkable that the hot iron was not applied parallel to the margin of the lid, but in five to six lines vertically from it, extending downwards. Trousseau had communicated a similar observation and cured ten cases in the same manner, with the only difference that he employed the thermo-cautery for the same purpose. According to the severity of the affection, the burning should be done more superficially or so deeply as to extend to the tarsal cartilage. The thermo-cautery, though much easier to use and handier, always gave the same result as the iron at white heat.

During the debate that followed this report, Trélat and Herin recommended to destroy the hair follicles of the margin of the lid by the aid of a fine needle at white heat. Trélat remarked that he always employed a magnifying glass, so as to be certain that he really reached the hair follicles. He had found this procedure uniformally successful, more reliable, and far less painful and disfiguring, than the actual cautery. He had also tried the galvano-cautery in such a manner as to make use of a platinum needle, which was brought to the required heat by a galvanic current, and thought that the result was still better, especially as he was enabled to pierce the hair-bag first with the needle ere he gave to the latter the required heat, thus, for certain, preventing injury to neighboring parts.

Excision of the Superior Maxilla.

Since it is well that we should know in what cases such an operation is justifiable, we note the conclusions of Dr. George A. Peters after reporting a case in the *N. Y. Med. Jour.*, January 17, 1885. This author considers the operation justifiable under the following conditions:

"Necrosis of the upper jaw, whether as the result of injury or disease in neighboring soft parts, syphilis, etc., requires operation, sometimes even to the extent of removal of the entire jaw.

"Non-malignant tumors of the upper jaw, as fibroma and enchondroma, occasionally attain a size requiring removal of the entire bone.

"*Hyperostosis of the jaw*, which consists primarily in periosteal inflammation, leading to the deposit of new bone and the expansion and filling up of the original osseous structure, is uncon-

nected with syphilis or struma, and appears to be beyond the control of remedies, and not infrequently reaches so great a size as to cause much deformity and justify the removal of the entire maxilla.

"It is in connection with malignant tumors of the upper jaw that the surgeon is often called upon to decide as to the propriety of removal.

"It is now well established by a large experience that the operation for cancer, even when so radical as the removal of the entire jaw, does not result in a cure, the disease being almost certain to recur. Nevertheless, the possibility of a non-recurrence, and the positive temporary relief afforded, in connection with the moral effect of the operation, will justify surgical interference."

Cure of Muscular Contracture.

Dr. Ferrier had a patient in whom, after an attack of pachymeningitis, a complete contraction of the flexor muscles of the right thigh developed itself. The contraction was so severe, that the calf of the leg pressed against the posterior surface of the thigh. He tried every known means to relax the muscles, but as he did not succeed in thus establishing a permanent cure, he had finally recourse to tenotomy, subcutaneously cutting all the sinews of the affected muscles. Afterwards passive and active motions and massage were employed, to keep the muscles in their normal position. (*Deutsche Med. Zeitung*, No. 99, 1884.)

When Ferrier reported the case, his procedure, and the result to the Paris Society of Surgery, Prof. Trélat rose and remarked, that while he could not but congratulate his colleague on the happy result of his case, he thought it wiser to guard such patients against the contracture which inevitably ensues in every case, where by carefully observing and controlling the position of the sufferer such a mishap is not prevented. In none of his cases had he ever had occasion to treat contracted muscles, but he was always careful not to allow them to lie in a strained position, or to bend forcibly their extremities. All these muscles should be kept relaxed, and a little attention to this rule was all that was necessary to prevent in any case of pachymeningitis the occurrence of contractures, a fact surely worth more than the most complete and satisfactory cure of a contracture once established.

Perchloride of Mercury as an Obstetrical Antiseptic.

Of late, perchloride of mercury has been the subject of considerable investigation as an antiseptic in midwifery, and the results have been very satisfactory. Professor Tarnier (*Archives de Tocologie*, July, 1884,) has reminded us recently how French researches on this point have been overlooked on the other side of the frontier. In a communication by Professor Kehrer, which has been lately published, the following results are arrived at:

1. Perchloride of mercury is the most powerful of all antiseptics.

2. A solution of one in a thousand has been shown to be sufficient to completely destroy the germinative power of microbes.

3. A solution of 1 in 100,000, added to liquids in which microbes were being cultivated, arrested their development.

4. A solution of 1 in 333,000 definitely arrests the development of the microbes. Out of 221 lying-in women, Professor Kehrer only observed four cases of temporary urticaria, and three cases of mercurial stomatitis in three syphilitic patients. In conclusion, the chief drawbacks of the sublimate are a roughening of the hands and easily rusting instruments, making sponges stiff, and giving a deep coloration to any small depressions of the skin. Prof. Kehrer warmly recommends the employment of perchloride of mercury during labor and lying-in.

The Relation Between Sick Headache and Astigmatism.

In the *Brit. Med. Jour.*, January 3, 1885, Mr. H. Bendelback Hewetson publishes a paper on this subject, and mentions six cases, as well as relating the notes of several others, in which patients of ages from 12 to 36 had been for many years the victims of periodic attacks of migraine. Between the attacks of migraine there had been chronic dyspepsia and vertigo in walking, in several of the cases. Two could bring on an attack of vomiting by sewing. All had some form of astigmatism, either mixed or compound, hypermetropic or myopic. All were completely cured by wearing proper correcting cylinders constantly. Mr. Hewetson believed that, when astigmatism of an abnormal character (or in some rare cases even a simple state of hypermetropia) existed in a neurotic subject, it might be the entire cause of periodic sick headache, with its accompanying dyspepsia, and could be cured by suitable glasses, constantly worn. Mr. Hewetson related Dr. Lauder Brunton's experience on this subject, but thought that the chief agent in producing this neurosis was the astigmatic element in the visual defect in most cases which had come under his

notice; and it evidently had little relation to the amount of an optical defect, unless that defect were complicated by astigmatism. Astigmatism in one eye, or eyes of varying degrees of optical error, would cause the same phenomena in neurotic subjects.

Periostitis Following Typhoid Fever.

It is not generally realized that periostitis is sometimes a sequela to typhoid fever, but Dr. John D. Hayward, of Liverpool, believes that it is a much more common occurrence than is usually supposed. During the past few years he has met with several cases which he notes in the *Brit. Med. Jour.*, Jan. 3, 1885.

In one case the periostitis did not suppurate, and the patient did well; in another, periostitis appeared about several of the long bones; suppuration occurred, with external discharge; but, after new attacks of periostitis had ceased to occur, and the old sinuses had healed (which they did readily), tho patient sank under acute phthisis, of which, previously to the enteric attack, there had been no evidence. The attacks of typhoid fever in which he has noticed this sequela have been severe ones.

With reference to the etiology, Dr. H. considers that it is possible that this local inflammation is due to the tendency to degenerative changes induced by the exhausted condition of the system after a severe enteric fever, resembling thus some of the commoner sequelæ of this fever. Or, there may be a septicæmic origin in some cases, just as some of the instances of parotitis, marasmus, and phthisis after enteric fever, are supposed to arise.

Bromide of Potassium in Diabetes Mellitus.

The use of bromide of potassium in diabetes has been recommended by Dr. G. Felizet; but Dr. Worm-Müller describes, in the *Norsk Magazin for Lægevidensk.*, a case in which the administration of this drug was not followed by success. The patient was a man aged 33, who came under Dr. Worm-Müller's care in February 1881. He had suffered from diabetes since 1880. The urine contained 5 per cent. of sugar. His diet was exclusively animal. On March 13 there was no sugar, and his weight had increased from 66 to 70 kilogrammes (about 145½ to 154⅓ pounds). He was allowed a little bread with his dinner. Little or no sugar was found in the urine, the same diet having been continued until October, 1882, when 1 per cent. was detected. The quantity of bread was diminished to one-half. The sugar remained unchanged. From Nov. 7 to 21, 40 grains of bromide of potassium were given; under its use the sugar rose to 3·4 per cent. The use of the bromide was then stopped; and on Dec. 1, the diet being exclusively animal, the percentage of sugar was 3·2. The author points out that the bromide of potassium had no influence in arresting the progress of the disease, even with an exclusively animal diet.

The Bacillus of Infantile Diarrhœa.

Truly the bacillus craze is being run into the ground. In the pages of our esteemed contemporary the *London Med. Times* (January 3, 1885), we read as follows:

"There seems to be no end to the varieties of bacilli. The latest addition to bacillology, if there be such a science, comes from France. At a recent meeting of the Societé de Biologie, MM. Clado and Damaschino announced that they had discovered the bacillus of infantile diarrhœa. This bacillus is about three times the size of the tubercle bacillus, and is six times as long as it is broad. It is a little curved, sometimes becoming crescentic in shape. The numbers found in any given case were in direct proportion to the severity of the disease. They were never found in the interior of the cells or epithelial masses, but always in the interstices. It was in the cases of green diarrhœa that the bacilli were found, and they disappeared as recovery took place, and the stools improved from green to yellow. The authors promise that they will shortly make known the results of their cultivation experiments, which are being vigorously pursued."

A Case of Thyroid Asthma.

Dr. Dardel (*Rev. Méd. de la Suisse Rom.* 8, '84,) observed severe attacks of asthma, apparently caused by an enlargement of the thyroid gland, in a little boy, æt. 13 months. After the child had happily escaped a number of seizures, it died in an attack of spasm of the glottis. At the post-mortem examination, besides the usual signs of death by suffocation, the following was observed. The trachea was remarkably narrow, especially where it was surrounded by the horseshoe-like shaped goitre. The thyroid gland, very voluminous, was pressed between the sternum and the trachea, and had caused with the latter many intimate adhesions. D. imagines that the asthmatic seizures were due to a peculiar spasm, first produced by the pressure of the tumor, and favored by the spasmodic nature of the laryngeal muscular apparatus. The disease is a very grave one,

especially on account of its changing character Treatment consisted of baths, derivants applied to the sternum, and tonics and anti-spasmodics, especially oxide of zinc and bromide of potassium.

Introspective Insanity.

Among those vague conditions of mental weakness in which there is slight derangement of the intellectual powers, yet a decidedly marked enfeeblement of the will, and an excitement of the emotions of a more or less limited kind, we find a variety of interesting psychoses which have, within a comparatively recent period, been considered under the names *folie du doute* or *grübelsucht*. And in an interesting clinical paper in the *American Journal of the Medical Sciences* for January, Dr. Allan McLane Hamilton treats them under the title of "introspective insanity." In the cases Dr. Hamilton relates there was a history of insanity, and the nervous temperament was manifested by various peculiarities, more often by a species of hypochondriasis, by peculiarities of temper, and by acts of eccentricity which caused the subjects to be looked upon as "queer." These terms are applied to the condition of mind which is manifested by a morbid feeling of doubt and consequent indecision under the most ordinary circumstances, when both the doubt and indecision are unreasonable in the extreme, but the individual under the mandate of an imperative conception yields more or less to his disordered emotions. Some years ago we would speak of this condition of mind as "hysteria," or, if it influenced the patient's conduct to any remarkable degree, we would be at a loss for a proper explanation.

A New Method of Diagnosing Pregnancy in the Early Months.

The sign on which Professor Hegar comments (*Annales de Gynécologie*, September, 1884,) is a peculiar softness, a certain subtileness, and a thinning of the lower segment of the uterus—*i. e.*, of the part of the uterus which is immediately above the insertion of the sacral uterine ligaments. This condition can be easily verified, not only when the uterus is resistant, as is usual, but still more so when it is elastic and soft. Even in these cases it is possible, by depressing the lower part of the uterus, to distinguish it from the superior portions, and from the rigid cervix. The softness of this part is such that one might imagine that the cervix was simply in contact with a pelvic or abdominal tumor. We do not know what pathological condition of the womb can present such symptoms. The cause of this remarkable sign exists in the fact that the inferior segment of the uterus becomes during pregnancy the finest part, the softest, and the most elastic. It thence results that, in practicing the rectal touch with abdominal palpation, it is possible to feel between the fingers this portion of the uterus, with the characters it presents.

Choice of Teeth for Extraction for the Purpose of Uniformity.

The *Weekly Medical Review*, November 15, 1884, says:

The physician is not always consulted relative to the best course to adopt in regard to the teeth, but he cannot afford to be ignorant of the peculiarities of this important part of the anatomy. When the teeth are too much crowded in the jaw, it is frequently desirable for æsthetic and hygienic purposes to draw some of them, and the question which to draw when there is a choice has, it appears, been a constant source of discussion among dentists. Dr. Perry, in order to throw some light on the subject, has tabulated 7,277 extractions for disease, and finds that 2,823 of these were first permanent molars, 737 were first bicuspids, and 944 were second bicuspids. As the statistics show that more first molars are lost than bicuspids, we should, as a general rule, take out the first molar where the choice must be, as is usually the case, between this and a bicuspid.

The Influence of Potassium Bromide on Nutrition.

The favorable results obtained from the use of potassium bromide in different nervous affections, particularly epilepsy, leads one to conclude that the nervous functions are influenced by this drug. B. Schultze (*Zeitschr. für Biologie*, No. 19,) made a series of experiments on himself, taking the bromide in ten-gramme doses daily for some days. He found a large increase in the volume of the urine on the day the drug was taken. The nitrogen excreted was determined in the urine and fæces, but the influence of the bromide upon its elimination was not marked; the sulphur, however, was found to be increased, and the phosphorus diminished. The author, therefore, concludes that under the influence of this drug the metabolic activity of the nerve-centres is diminished, this being accompanied by a decided diminution of the nervous activity.

A Simple Method of Washing out the Bladder.

In the *Lancet*, October, 1884, p. 675, Mr. Buckston Browne describes a simple method by which

a patient can wash out his own bladder. A diagram is given which helps to explain the action of the instrument. A simple bifurcated brass tube, without valve or stopcock, has one end fixed to a Higginson's syringe; the nozzle is fixed at the other end to a catheter in the bladder. The fluid is gently injected into the bladder by squeezing the ball of the syringe, whilst a finger is placed over the open end of the bifurcated tube; when the finger is removed the contents of the bladder escape, or fresh injections can be made into the bladder, and then allowed to flow away at pleasure. By this means a patient is able to wash out his own bladder with ease.

Vesico-vaginal Fistula with Inverted Bladder.

The details of this case, which is believed to be the only recorded instance of a bladder inverted through a vesico-vaginal fistula, are given in the *New York Medical Journal*. The patient, aged 47, was admitted on October 11, 1881. She was married at 25, and had one child still-born. The labor was instrumental, and incontinence of urine occurred soon after it, 20 years ago. She had never sought relief for this, and spoke of her present suffering as having begun only one year before admission. During this period, however, the pain had been so intense that she had not been able to leave her bed. There was constant pain in the lower part of the abdomen, the bowels were constipated, appetite poor; nausea and vomiting were almost constant. The urine was pale yellow in color, sp. gr. 1002, alkaline, and contained a trace of albumen; the quantity could not be estimated. She was examined under ether on October 29. From a large opening in the vesico-vaginal septum there protruded a bright red, round, exquisitely sensitive tumor, which was found to be the inverted bladder. The exposed mucous membrane was much inflamed, and bled readily on being touched; the openings of both ureters could be distinctly seen. The mass was reduced by gentle taxis, and was retained by the support afforded by a Skene's glass stilette made to pass through the urethra, with its extremity resting upon the upper border of the fistulous opening. A vaginal glass plug was also introduced to aid in supporting the bladder.

On November 30, the inflammatory condition of the parts having now somewhat subsided, the edge of the fistula which was about 5 cm. (2 inches) in diameter, was carefully pared and bevelled from the vesical margin, and twelve silver sutures introduced. Before closing the fistula it was found necessary to liberate adhesive bands at either angle. A self-retaining catheter was introduced, and the patient was given one-sixth of a grain of morphia subcutaneously, and ordered lime-water and milk every two hours. There was subsequently much vesical tenesmus for a day or two. The sutures were removed on December 7, union was imperfect at either angle, and in the centre was a small patulous opening. A second operation was performed on January 6, after which the left opening—situated just at the site of the ureter—alone remained patent, just admitting a Snelling's probe. Three subsequent operations, on January 20, February 3, and March 28, failed to close the opening. During each of these operations a probe was passed through the urethra into the ureter, so as to prevent wounding or obliterating the latter. The patient returned home on May 8, 1882, and after some months urine ceased to pass through the opening in the septum, probably owing to the contraction of the cicatricial tissue.

Mumps as a Cause of Sudden Deafness.

Disease of the ear during the progress of acute infectious disorders is a not infrequent occurrence. Especially are suppurative inflammation of the middle ears common during the progress of scarlet fever, and non-suppurative inflammations are a frequent attendant upon the progress of measles. The nature and treatment of these ear diseases are well understood. But occasionally during the progress of mumps a sudden and complete loss of hearing occurs which is not so well known, either as to its nature or its treatment, and a paper on the subject from the pen of Dr. Leartus Connor, of Detroit, which appears in the October number of the *American Journal of the Medical Sciences*, is both timely and instructive.

As the result of his personal experience and of the study of thirty-three recorded cases, Dr. Connor concludes that—

1. Mumps do in some rare cases produce complete deafness.

2. This deafness is usually attended with all the evidences of disease of the labyrinth.

3. These show that it sometimes begins in the cochlea, but more frequently in the semi-circular canals.

4. Owing to the lack of early observations and treatment it is impossible to say that it is not transmitted through the middle ear from the parotids to the labyrinth.

5. The history of some of the cases would seem to suggest that such an origin was possible.

6. This possibility renders it very important

that every case of deafness during an attack of mumps be at once carefully examined, so as to settle the question.

7. This possibility offers the only hope for the successful treatment of these cases so as to prevent deafness. Thus, if there be a middle ear disease, we might hope that revulsive and counter-irritant treatment would arrest the disease and save the labyrinth.

8. As to the treatment of the labyrinthine disease nothing has thus far been devised that has produced any satisfactory result.

Dry Cupping in the Treatment of Anthrax.

Dr. E. I. Thorn writes as follows to the *Medical Record*, January 17, 1885:

"Upon the appearance of one or more of the small ulcers at the apex of the tumor, apply the cup after inserting a lighted taper moistened in turpentine. In a moment this will open the cells, and there will exude into the cup a teaspoonful, more or less, of sanious pus. Follow this operation with poultices to keep up the discharge, and in a few days the carbuncle will disappear. In this way we avoid from three to six weeks of suffering, and the constitutional results of the usual protracted illness."

Correspondence.

Hamamelis in Epistaxis of Typhoid Fever.

Eds. Med. and Surg. Reporter :—

Henry B. English, æt. 22, a railroad laborer, had been complaining of the usual symptoms of typhoid fever for several days. While sitting in his chair one afternoon he felt as though "something had exploded in his nose," which was followed by a profuse epistaxis of a violent nature. He called at my office at 4 p. m. On examination, I found blood running down over the soft palate in intermittent jets, and oozing out at the anterior nares around the temporary plugs of cotton he had placed in his nostril. I introduced some nasal plugs, freshly saturated with tannic acid, which checked the bleeding immediately and appeared to be permanent, but only proved to be temporary. I then resorted to the remainder of this class of astringents—alumen, gallic acid, etc., subsulphate of iron being the only ferruginous preparation resorted to. I then left my patient, telling him that I would call again in about an hour, this being 8 p. m.

On returning, I found my patient in the same precarious condition as he was when entering my office, the subsulphate of ferrum having failed to be of any therapeutical value in this case.

I then removed the old plugs and replugged the anterior and posterior nares with freshly-made ones of absorbent cotton. He assured me that he would die, for his strength was failing fast, and what assistance could be given must be rendered immediately. I examined his pulse, found them weak, irregular, and his life in great jeopardy. I remembered of hearing of the hemostatic properties of hammamelis while attending lectures. I prescribed the fluid ext. in ʒss. doses every fifteen or twenty minutes, as the emergency of the case demanded. The epistaxis was controlled immediately.

His typhoid developed in a very few days. He passed through the entire attack without a single instance of the hemorrhage returning, and was convalescing, when he had perforation of the bowel, and died before medical aid could be summoned.

The point I wish in this case is to point out the valuableness of hamamelis over other astringents and styptics in this case of epistaxis.

Wm. T. Easley, M. D.

Coffeen, Ill.

News and Miscellany.

Official List of Changes of Station and Duties of Medical Officers of the United States Marine Hospital Service, Oct. 1, 1884, to Dec. 31, 1884.

Bailhache, P. H., surgeon. Granted leave of absence for thirty days, Oct. 9, 1884. To proceed to Wilmington, N. C., as inspector, November 10, 1884. Relieved from duty as chief of Purveying Division; to proceed to Philadelphia, Pa., and assume charge of the service Dec. 10, 1884.

Wyman, Walter, surgeon. Granted leave of absence for fifteen days, Oct. 15, 1884. Leave of absence for fifteen days in December, 1884, and thirty days in January, 1885, also for a further period from January 31, 1885, without pay, and with permission to visit Europe, Dec. 8, 1884.

Purviance, George, surgeon. When relieved to proceed to Cincinnati, Ohio, and assume charge Nov. 12, 1884. To Louisville, Ky., as inspector, Nov. 24, 1884.

Austin, H. W., surgeon. To proceed to Boston, Mass., and assume charge, Nov. 12, 1884.

Smith, Henry, surgeon. When relieved to proceed to Cairo, Ill., and assume charge Nov. 9, 1884. Granted leave of absence until January 15, 1885, Dec. 17, 1884.

Stoner, G. W., passed ass't surgeon. Relieved from duty at Delaware Breakwater Quarantine, to proceed to Cairo, Ill., in accordance with former orders, Oct. 14, 1884. To Norfolk, Va., Nov. 19, 1884.

Irwin, Fairfax, passed ass't surgeon. To close Cape Charles Quarantine Oct. 31, 1884, proceed to Washington, and report to Surgeon-General, Oct. 14, 1884. To take charge of the service, port of Georgetown, D. C., and detailed as Acting Chief-clerk, Surgeon-General's Office, Oct. 30, 1884. To Philadelphia, Pa., and Baltimore, Md., as inspector, Dec. 30, 1884.

Mead, F. W., passed assistant surgeon. When relieved, to proceed to Baltimore, Md., and assume temporary charge, December 10, 1884.

Heath, W. H., passed assistant surgeon. Granted leave of absence for thirty days on ac-

count of sickness, October 24, 1884. When relieved, to proceed to Pittsburgh, Pa., and assume charge, December 26, 1884.

Guitéras, John, passed assistant surgeon. To report to Surgeon-General, November 8, 1884. Leave of absence extended fifteen days, without pay, November 14, 1884.

Wheeler, W. A., passed assistant surgeon. Relieved at Chicago, Ill., to proceed to Buffalo, N. Y., and assume charge, December 26, 1884.

Banks, C. E., passed assistant surgeon. When relieved, detailed for special duty; upon completion of same, to Boston, Mass., for duty, October 28, 1884.

Peckham, C. T., passed assistant surgeon. Granted leave of absence for twenty days, December 26, 1884.

Bennett, P. H., assistant surgeon. When relieved, to rejoin his station (Detroit), November 20, 1884.

Ames, R. P. M., assistant surgeon. To report to Surgeon Hutton, at Louisville, Ky., for examination for promotion, November 13, 1884.

Devan, S. C., assistant surgeon. To proceed to Tacoma, W. T., as inspector, October 14, 1884.

Kalloch, P. C., assistant surgeon. Granted leave of absence for thirty days, November 19, 1884.

Glennan, A. H., assistant surgeon. To proceed to Key West, Fla., for temporary duty, October 8, 1884.

Battle, K. P., assistant surgeon. Granted leave of absence for thirty days on account of physical disability, December 6, 1884.

Brooks, S. D., assistant surgeon. To proceed to New York, N. Y., for temporary duty, October 20 and November 26, 1884.

White, J. H., assitant surgeon. To proceed to New Orleans, La., for temporary duty, October 3, 1884. To escort insane seamen to Government Hospital for the Insane, December 17, 1884. Granted leave of absence for fifteen days, December 23, 1884.

RESIGNATION.

Smith, Henry, surgeon. Resignation accepted by the Secretary of the Treasury, to take effect January 15, 1885, December 17, 1884.

APPOINTMENT.

White, Joseph H., M. D., of Georgia, having passed the examination required by the Regulations, was appointed an assistant surgeon, by the Secretary of the Treasury, October 2, 1884.

PROMOTIONS.

Peckham, C. T., passed assistant surgeon, promoted and appointed passed assistant surgeon by the Secretary of the Treasury from December 1, 1884, November 28, 1884.

Ames, R. P. M., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury, from December 1, 1884, November 28, 1884.

Devan, S. C., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury, from December 1, 1884, December 5, 1884.

Urquhart, F. M., passed assistant surgeon. Promoted and appointed passed assistant surgeon by the Secretary of the Treasury, from December 1, 1884, December 5, 1884.

The Investigation of Chorea.

Dr. Dyce Duckworth, in opening a discussion on chorea (*Brit. Med. Jour.*, January 3, 1885), says:

"Permit me, then, to state the points on which further knowledge is desirable.

"First, it is required to have a much larger number of cases from which to deduce facts.

"Secondly, the ages and sex of the patients are wanted in all cases, and every case in each reporter's practice should be taken note of, for without this, a fallacy may come in, respecting the incidence of chorea on different classes of patients.

"Thirdly, information is sought as to the general prevalence of the disease in different districts.

"Fourthly, under the head of exciting causes, it is of the last importance to be exact as to the nature of these, and the interval between the exciting cause and the onset of choreic symptoms.

"Fifthly, more complete information is desirable as to the condition of the heart at the beginning, in the progress of, and after the disorder has passed off. It is very important to secure records not only of the state of the heart a few years after attacks of chorea, but also of the subsequent general life-history of such patients. The latter, indeed, has equal significance with the antecedents of these cases.

"Lastly, more knowledge is sought as to the common ailments to which choreic patients are liable. It ought to be possible to determine the average duration of choreic attacks. My colleague, Dr. Andrew, has gathered from a study of cases that this is somewhat over ten weeks—about ten weeks and three days. With gaps such as these in our stock of knowledge respecting chorea, we may rightly feel that there is still much for us to do. To-night, then, I direct your attention to these several points, and beg you to pursue them in your respective fields of observation."

The Application of Dentistry to the Detection of Crime.

Mr. Robert Reid (*Journal of British Dental Association*, Sept. 1884,) enlarges upon this subject, and publishes an instructive case of murder. The room where the murdered man had been struck down was strewn with detached portions of the upper jaw bone, the largest of which extended from the second bicuspid on the left side to the canine tooth on the right, inclusive. The alveoli of the right and left upper laterals were occupied by left central and lateral incisors of the lower jaw. Among the detached teeth were right and left upper lateral incisors, corresponding exactly in shape and size with their fellows. On examination of the accused person, his central and lateral incisors of the left side of the lower jaw were found to have been recently removed, and the corresponding teeth removed from the jaw of the deceased were found to fit into the proper alveolar cavities of the accused.

—Dr. Andrew F. Currier contributes to the *New York Med. Jour.*, January 10, 1885, an interesting paper on "Gonorrhœa in the Female."

Japanese Teeth.

Before the Odontological Society of Great Britain (December 1, 1884), Dr. St. George Elliott exhibited and presented to the museum some very curious artificial dentures of Japanese manufacture. These people had derived most of their technical and scientific knowledge from the Chinese, but, in this matter, they were far in advance of their teachers; for, whilst the latter could only carve a row of incisors and fasten them to the teeth on either side, the Japanese could make thoroughly serviceable dentures, and had been acquainted with the method of fixing them by suction for about two hundred years. The teeth were mounted on hard wood, those in front being made from quartz pebbles carefully ground down, but the process of mastication was performed by copper nails which occupied the place of the molars. One of these dentures had been in use for fifteen years. Dr. Elliott gave a very interesting account of the way in which they were made and fitted.

Tribute to Professor Gross.

The Æsculapian Society of the Wabash Valley, at its annual meeting, passed resolutions of respect to the memory of Prof. Gross, and of appreciation for his long and brilliant career in the labor and literature of the profession.

Items.

—Busk has discovered osteo-arthritic lesions in bones found at Gibraltar, which must have belonged to bears of the glacial period.

—Dr. O. S. Taylor, of Auburn, N. Y., completed his one hundredth year on December 17. He graduated from Dartmouth College in 1809, and from the Medical College in 1813.

—It is said that the reason more physicians in France did not use *Kochsalz infusion* as a treatment for cholera was because they thought it had something to do with the discoverer of the cholera bacillus.

—Dr. Lathrop A. Willis, of Brooklyn, died January 2, in his sixty-first year. He was a graduate of the Albany Medical College, of the class of 1849, and a member of the Medical Society of the County of Kings.

—Indet (*Gaz. des Hôp.; Centralbl. f. Gyn.*) has employed phosphated peptone successfully in cases of vomiting that had resisted other treatment. He gave six tablespoonfuls of the peptone phosphate, and subsequently increased the dose to twelve tablespoonfuls.

—Dr. Ambrose L. Ranney, professor of applied anatomy in the New York Post-Graduate Medical School and Hospital, has been appointed to the chair of anatomy in the medical department of the University of Vermont, made vacant by the death of Professor Darling.

—The *Lancet*, January 3, 1885, says that the oil of peppermint would appear to be a useful application for burns, according to Dr. Brame. The part burned is first immersed in water, and then the oil is painted on by means of a fine camel-hair pencil. The chief effect is the immediate relief of the pain.

—A department of hygiene and the science of micro-organisms has been opened in connection with the chemical laboratory of Prof. Fresenius, at Weisbaden. Dr. F. Hueppe, who has done much work under Dr. Koch at Berlin, has been appointed to the charge of this department.

—The "faith cure" seems to have met with a check, if we may judge by the report of a recent recommendation by the Grand Jury of Denver that an asylum in that place, devoted to carrying out this particular form of treatment, should be closed, on account of three deaths having taken place in it from inanition since Christmas.

—The *Cinn. Lan. and Clinic* (October 4, 1883), says that pruritus ani and the distressing itching of urticaria and mosquito bites can be much alleviated by local applications of menthol. It may be used by rubbing the menthol pencil lightly over the surface, or by dissolving a small amount in alcohol and bathing the part.

—The *Lancet* credits M. Trastour with a communication to the *Gazette Médicale de Nantes*, in which he speaks highly of glycerine in obstinate coughing. He evaporates two ounces of glycerine in a flat dish, and allows the patient to inhale the vapor. Carbolic acid may be added with advantage. The treatment is specially applicable to phthisical patients.

—A State Board of Medical Examiners of North Carolina, its members appointed by the State Medical Society, has been in existence since 1859. No person can practice medicine or surgery without a license from this Board. Although the law provides no penalties, a recent report states that it has accomplished good results in weeding out quacks and forming a healthy public opinion regarding that class.

—At the recent annual meeting of the College of Physicians of Philadelphia the following-named gentlemen were elected to office:

President—Dr. J. M. DaCosta.
Vice-President—Dr. S. Weir Mitchell.
Secretary—Dr. Richard A. Cleemann.
Treasurer—Dr. Charles Stewart Wurts.
Honorary Librarian—Dr. J. H. Hutchinson.
Recorder—Dr. J. Ewing Mears.

—M. Michel, a medical man practicing at Chaumont, in a note to the Académie des Sciences of Paris, publishes evidence confirming the accuracy of M. Marey's communications concerning the part played by water in spreading epidemics. It appears that every year there were a considerable number of deaths at Chaumont from typhoid fever. Recently, a water-supply, which was believed to be contaminated, was cut off; since that time, typhoid has disappeared.

—Dr. Dureau de Villeneuve, in a note presented by M. Marey to the Académie des Sciences of Paris, recommends that distilled water should be generally used for drinking purposes. He argues that pure water is a desideratum, especially during cholera epidemics. Distilled water fulfils this condition, and could be easily obtained by utilizing the condensers of the different steam-engines kept at works. Dr. Villeneuve suggests that water thus distilled should be distributed among the inhabitants of the different districts near the seat of distillation.

—In the *British Med. Jour.*, January 3, 1885, Dr. Elliott relates the case of a patient who had been under his care for dislocation of the elbow forwards and comminuted fracture of the olecranon. Passive motion was commenced in the fourth week, and adhesions afterwards broken down under chloroform. To the comparatively early adoption of these measures, he attributed the freedom from rigidity and almost perfect movement in the joint.

Stephan (*Allgem. Med. Centr. Ztg.; St. Petersburgh Med. Woch.*) says that the application of ice-bags over the supra-clavicular regions during fever is followed by a marked reduction of the temperature. In several cases of typhoid fever treated in this manner he was able to control the fever, while the sensorium remained clear. The explanation offered is that many large superficial veins are situated in the neck, and that by the direct application of heat to them the temperature of the blood is lowered rapidly.

—At the annual meeting of the Paris Cremation Society, the President, M. Koechlin Schwartz, stated that the law proposed by MM. Gambetta, Paul Bert, Tony Révillon, and many Republican deputies, is not yet passed. Cremation remains at present illegal in France. It was generally suggested in the report that there was nothing to prevent cremation in the hospitals. The President insisted on the great security for the public health by the adoption of the system, and mentioned that in Italy there had been 396 cremations, and in Germany 186. The tariff for the transport of corpses to Italy for cremation was circulated. It is rather high, and can only be resorted to by rich families.

—A writer (*St. Louis Medical Journal*) has had a so-called oleate of chloral made, which, he says, has been used with much success in pruritus ani, eczema, and other affections associated with much itching. The compound consists of one drachm each of camphor and chloral, and one ounce of oleic acid, thoroughly mixed together. Camphor and chloral in equal parts, forming a liquid, has long been known as a valuable remedy in cases where local anæsthesia of the cutaneous nerves is desired, and has been employed in neuralgia and pruritus. The addition of the oleic acid will undoubtedly increase the penetrating power of the mixture. It may thus be found useful in allaying the itching, while other means are employed to secure permanent relief.

—Here are two current news items which present a startling yet altogether logical comparison. Massachusetts last year enjoyed an almost total immunity from small-pox, but nine cases, with only one death, having been known to occur in the entire State in a twelvemonth. In Kashmire the mortality during the year was of almost incredible proportions. The history of twenty-five families was recently taken, in which it appeared that, out of 190 persons, 100 died of small-pox. In Kashmire there is no vaccination; in Massachusetts it is absolute, compulsory, and as general and systematic as tax-paying. Peace hath its victories. If modern medicine had done no other single thing than demonstrate its control of one of the most terrible of human ills, it would be deservedly honored.

—Before the Sheffield Medico-Chirurgical Society (December 4, 1884), Mr. Atkin read the notes of a case of congenital coccygeal tumor. The growth sprang from the right side of the sacrum and coccyx, the bone on the left being deficient. Double talipes equino-varus was also present. Microscopic sections of the growth were shown, when it was seen to be of a very mixed character; fatty, fibrous, and cartilaginous elements were seen, as well as well-marked ducts, lined with columnar-shaped epithelium; cysts were also present, interspersed among the fibrous tissue, containing a semi-opaque, yellowish, granular material. Mr. Atkin made remarks on the different descriptions that had been given as to the pathology of these tumors, and laid stress on the total absence of anything that might be considered sarcomatous.

The practical conclusion to be drawn from these cases is, that reliance cannot be placed upon a single examination of the urine, but that in any doubtful case of chronic disease it is our duty to examine the renal secretion repeatedly, noting whether albumen appears after a heavy meal of flesh, and whether the urine of abstinence is of abnormally low specific gravity. I have seen patients who certainly did not have Bright's disease, but in whom an irritant drug or an alcoholic excess would produce albuminuria. It is to my mind very probable that such people will eventually develop renal disease. At any rate these cases have suggested to me that possibly as we employ purgatives to make a so-called therapeutic test in a case of suspected typhoid fever so we might use cantharides, turpentine, or other irritant drug in a case of suspected Bright's disease. If on trial it should be found that a slight irritation would seriously affect the urine, the case should be looked upon with the greatest suspicion.

QUERIES AND REPLIES.

Eds. Reporter:—

I noticed in the Reporter some weeks ago, a remedy for nose bleeding, namely, a piece of salt pork passed up the nostril. Since reading the article, I have tried it in three different cases without the slightest effect. Probably the altitude at which I live (7,500 feet) may have something to do with its failure to act. I use the injection of the solution of the persulphate of iron up the nostril, and it acts in "great shape." Yours truly,

Alex. Hazard, M. D.

Eds. Reporter:—

In your issue of December 6, 1884, article, "Treatment of Lupus," I desire to know at what time the scraping is done with the spoon? Is it immediately after making the application, or some hours afterwards? J. S. D.

Ans. The scraping is done first and the caustic then applied.

Eds. Reporter:—

In a case of complete obstruction of the bile ducts (hepatic and cystic), how long should a patient, an otherwise healthy adult male, expect to live, and what will be the immediate cause of death without intercurrent disease.

G. F. J.

Ans. This question cannot be answered with any degree of authority as to the duration of life. The cause of death would probably be cholestoremia.

ORIGINAL DEPARTMENT.

LECTURE.

ABSTRACT OF A LECTURE ON PSORIASIS, DELIVERED AT FRANKLIN HALL, JERSEY CITY, N. J.

BY JOHN V. SHOEMAKER, A. M., M. D.

Mr. Chairman and Gentlemen of the Hudson County Medical Society: Permit me to express many thanks for the invitation to speak before your society upon this occasion. I greatly appreciate the opportunity you have thus given a brother practitioner of meeting the members of a society who are so well known by the profession at my home. I have, however, a great hesitation in talking upon a subject that is so familiar to the veteran members of the profession who are present at this time. I observe in the room one gentleman in particular, Prof. Alfred Post, one of the oldest and most proficient clinical teachers in the country, before whom I am still more reluctant to speak upon the subject selected for this afternoon's discussion. I hope, however, that you as well as our distinguished friend will bear with my shortcomings, while I endeavor to briefly describe psoriasis in a clinical manner, from two cases brought from the Philadelphia Hospital for skin diseases. The first patient, this young boy fifteen years of age, has, as you will observe, an eruption on the scalp, face, arms, and hands, with a few spots scattered over the body, which appeared almost one year ago. The spots have always been dry, never disappeared, but have gradually during this time become more marked. The majority of them are about the size of an ordinary pea, being red, slightly elevated, and some of them are covered with dry, white scales. On the scalp, forehead, and dorsal surface of the hands, the eruption is more marked. It is also present not only in the form of the patches just alluded to, which has the appearance of drops of mortar, hence called psoriasis guttata; but there may also be seen smaller spots about the size of a pin's head, which is usually spoken of as psoriasis punctata. The eruption generally appears in the form of these latter slightly elevated, round, and reddened spots, and increase in size to the former, which are present here in large numbers. The larger as well as the smaller patches are separated by intervening healthy skin. The scales have been washed or dropped off, to a large extent exposing the dry, reddened spots raised above the level of the skin.

In the next patient, a man of forty-eight years of age, the eruption is seen over the general surface, being termed psoriasis diffusa, or psoriasis universalis, and the symptoms will be found to be even more striking than in the first case. A few of the patches similar to those in the first patient can be recognized, as well as many others having all sizes and shapes. Here are some on the back and arms having the appearance of the ordinary coin-psoriasis nummularis, or circumscribed in form-psoriasis circumscripta, and others being disk-like are named psoriasis discoidea. Again bands of the eruption may be seen on both the chest and back, and are thus termed psoriasis gyrata. The eruption begun, as the patient points out, by the appearance of these small, slightly elevated spots about the size of a pin's head, covered with dry white scales, and so spread until the entire body became covered with the disease.

The spots on the back and limbs will be seen to be somewhat separated by intervening healthy skin, but the abdomen is one immense patch of deep infiltration. The patches are also well marked on the extensor surfaces and the scalp, which regions are favorite localities for the development of the eruption. The scales have been exfoliated almost from all the patches, leaving the surface red, elevated, and tender. Large quantities of the cast-off scales, the patient states, are usually in his bed-clothes and under-clothing.

A close examination of the scalps of both patients will show that while the eruption is well marked, yet the hair has not fallen out, but has retained its natural lustre and color. In the second case it will be seen that the disease has affected the nails, which do not extend beyond the ends of the fingers; they are also thick, rough, lustreless, brittle, fissured, and are brownish in appearance.

The eruption in some cases may continue throughout its course in the form described in the first case, or it may spread either gradually or rapidly to certain parts or over the whole surface, as in the present case. It may also remain without change throughout the patient's life, or by treatment the surface may assume its normal appearance without any pigmentation or scarring, to again, very often, crop out even in a more severe form.

It will be noticed in both these cases that itching, which was present at the first appearance of the eruption, has now entirely subsided. Itching may be entirely absent, or the disease may be attended with it in its early development, and subside with the persistence and extension of the eruption.

While the eruption upon these cases might resemble many other cutaneous diseases, yet they are more likely to be mistaken for eczema squamosum and syphiloderma. In the former disease the primary lesion is erythematous patches, vesicles or pustules, which are succeeded by moist spots, crusts, and scales, the latter not being white or silvery in appearance, and being situated on bright red patches—by preference on the flexor in place of the extensor surfaces, and itching, which is usually marked, lasts throughout the entire course of the disease. On the other hand, in these cases, the primary lesion was the masses of epidermic scales and the scales that can be seen are white or silvery in color, and are situated on dark red patches located by preference on the extensor surfaces. Further, the symptom of itching, which was slight, was only present when the patches first appeared, and soon subsided. The squamous and papular variety of syphilis of the skin might also be confounded with this eruption, especially in its early stages. The scales in syphilis will be seen to be of a dirty color, and the red spots on which they rest extend beyond them, while in these cases the scales are whitish or silvery in appearance, and in some of these spots still intact, they extend beyond the red bases which they cover. The absence in both cases of the preceding evidences of syphilitic fever and the long chain of symptoms common to it, together with the absence of pigmentary stains, scars, mucous patches, and enlarged lymphatic glands, would be additional conclusive evidence against the patient's being afflicted with a syphilitic skin affection.

The pathological changes in psoriasis are well demonstrated in the section that has been made from the second case, which is now placed beneath the field of the microscope, and will be passed around for your examination. You will observe from this section that the epidermis is greatly developed, the papillary layer of the derma is somewhat enlarged, being filled with cells, the blood-vessels are dilated, the glands are normal, but the hair follicle is changed, the external root-sheath being increased in size, and the connective tissue of the derma is the seat of considerable infiltration. It has been shown that these inflammatory changes just pointed out begin primarily in a hyperplasia of the rete and the external root-sheath, the cutis being involved secondarily.

The cause of the appearance of this disease in these patients can probably be more clearly demonstrated by questioning them and receiving their answers. I will first inquire into the history of the boy.

How long has this eruption been on your body?

About one year.

Have your habits been good?

Yes, sir.

Have you any idea of the cause of this eruption?

No, sir.

Have you always been well?

I have never been sick, but I have some pains at times around the upper part of my body or in the arms.

How long have you noticed these pains?

Can't remember.

Did they come before the eruption?

I think they did.

Have you ever tried to get relief from the pains you refer to?

No, sir; I concluded they were growing pains.

Point out how and on what part of your body these spots first appeared?

They came first on my scalp and then on the arms, in this way (the patient pointing out the small red, isolated spots about the elbow and wrist).

I next pass to the second patient. Will you give your age; mention if your habits are good, and if you ever had any disease; when and upon what part did this eruption first appear, and do you know what could have caused it?

I am forty-eight years of age; I work steady at my trade—a machinist—and have always been healthy, except this trouble. This skin disease began eighteen years ago on my shin, and soon covered the whole body. Several doctors have cured me at different times, but it comes back again. I think my rheumatism has caused it.

How do you know it is due to your rheumatism?

I believe you told me.

Did you not say frequently when I questioned you that you never had rheumatism?

Yes, sir.

From the personal history of these cases you can surmise the cause of the psoriasis; the rheumatism, no doubt, keeps the disease active in both of the patients.

It might be of interest for you to know that the second patient repeatedly denied that he ever had rheumatism; but seeing his joints swollen one day, I inquired if he had been in this condition upon any previous time. "Yes, sir," he answered; "I often take cold in this way, but it soon passes off."

You will therefore see he did not comprehend, as many patients similarly affected fail to do, what was meant by the word rheumatism.

It will be found upon a close observation of many cases of psoriasis that either rheumatism or gout are frequently the exciting cause of the disease. The accumulation in the blood of certain excrementitious substances, either from these or other diseases, may develop psoriasis.

The speaker alluded to the views of those who believed the disease was the result of syphilis, and pointed out how different the eruption was from syphilitic skin affections, and that the mercurials and iodides that acted decidedly upon the latter had little or no impression upon psoriasis. The parasitic nature of the disease originated by Lang was mentioned, but the theory was shown not to as yet have been received with much favor.

The aim of the treatment in both cases that have been before you will be to remove, if possible, the rheumatism by the employment of suitable remedies for it.

In case of the boy, the following prescription has been found to lessen the pains: Salicylate of soda, 100 grains, and two ounces each of the sweet spirit of nitre, and the infusion of digitalis; one to two teaspoonfuls of this mixture should be taken in water three or four times daily.

The second patient is now taking, with advantage, the following prescription: Sweet spirit of nitre, two ounces; two ounces each of infusion of colchicum and infusion of digitalis; and aloin, five grains. From one to four teaspoonfuls of this combination is taken four times daily. An occasional mercurial or saline purge will also be of advantage in both cases. If the rheumatism and the eruption in both instances will not vanish under the internal medication and the employment of the local means presently to be mentioned, I will then give small doses of arsenic, for its nutritive effect upon the system. Arsenic is of no benefit in the acute stage of the eruption, and should only be employed in the later stages, and then it should be pushed until a decided impression is made upon the system. In giving arsenic, I usually employ arsenious acid or sodium arsenite in about one-twentieth of a grain dose three times daily, in preference to the solutions of arsenic, which are often improperly prepared or have become deteriorated by being kept on hand for some length of time. In case of long-standing psoriasis, the arsenic can be made to act more promptly by giving it hypodermically, the sodium arsenite being used in from one-twentieth to one-half a grain, injected once daily.

In treating the majority of cases of psoriasis, the alimentary canal, the kidneys, and the skin, should be made active to remove from the system the elements that are keeping active the disease. By treating the exciting cause, pouring out the waste products in the manner just named, and by the nutritive action of the arsenic, should it become necessary to administer it, psoriasis can be controlled. There is no specific for psoriasis, either in arsenic, the tincture of burdock seed, or chrysarobin, so highly recommended by Napier. The latter has a purgative action given internally, and will in that way cause the eruption to pale, just as any other purgative would do administered for some time. In addition to the internal treatment, which is all-important, and upon which I always place the most dependence in, hoping to

permanently affect the disease, is the use of local means. The most important local means to use are baths: the hot air, the vapor, the simple water, and medicated; and by their employment the skin is made active, the effete products are poured out, and the system is thus relieved of the elements that conduce to keep up the disease.

Finally, the use of either chrysarobin or chrysophanic acid, one of the mercurials, tar, carbolic acid, naphthol, and thymol in the form of a fixed dressing, or by the incorporation of one of them in a fatty substance and applied to the skin, often acts rapidly in removing the infiltration; but the eruption will again return unless the cause for its existence in the system has been eradicated. I consequently place very little reliance upon these stimulating remedies that but act for the time.

COMMUNICATIONS.

SOME OF THE COMMON DISORDERS OF INFANCY AND EARLY CHILDHOOD.*

BY G. A. HILL, M. D.,
Of Williamsport, Pa.

Probably no one who has devoted years of thoughtful study and attention to the maladies of infant life will but agree with me that herein are found much that is peculiarly instructive and interesting.

From the first cry of the new-born babe to the years of independent thought and speech, there is a volume of absorbing interest, worthy the most careful study of any physician. The helpless suffering of the little patient, the plaintive cry and looks of distress, his only language to express his perturbed sensations, his pallid face and eyes filmy and sunken, or a countenance gleaming and restless, with the flush of exalted temperature—all these call in language intense and eloquent for sympathy, and must forcibly remind the physician of the responsibility he has assumed.

I have heard it frequently asserted that, owing to the obscurity of diagnosis and enforced medication, drugs can be of little avail in the diseases of early childhood. I think—indeed, I am sure—taken in a general way this is a mistake. True it is that our diagnosis must rest solely upon subjective signs, except perhaps in lung troubles, but it is at the same time true that these subjective signs are not rendered doubtful or obscure by wilful or ignorant misrepresentations. We have no prejudices, no false modesty, no concealment of facts to deviate the current of diagnosis. If we carefully scrutinize the countenance, note the cry, the gestures, and give due regard to the general behavior of the child; if we are careful to learn something of his previous habits and management, and likewise study attentively the skin, the eye, the pulse, the ejecta, and all those various other phenomena that yield their share of information to the observant mind, there can, I think, be little reason to hesitate in coming to a satisfactory conclusion. It might be well to mention a not infrequent source of mistaken identity in the complaints of childhood. The mother or nurse, in her lack of the proper appreciation of existing conditions or by her over-anxiety to impress the physician with their seriousness, is liable to make statements which are not strictly true.

Many children are born into the world with constitutions vitiated or weakened by hereditary taint and thus afford a favorite seat for subsequent diseases; but however desperate seems to be the outlook in these cases, we are culpable if we give way to untimely despondency. I believe more than one infant has been sacrificed upon the altar of a discouraging prognosis, when a successful issue demanded only hearty and persistent effort in the right direction. It is well known that children have a more tenacious hold upon life than adults; the springs of existence are in them more elastic, and sometimes rebound quite unexpectedly to the touch of skill and experience.

It is not my design, nor would it be possible, to treat exhaustively of this great subject of the pathology of infant life within the limits of this paper; as my heading indicates, I shall attempt nothing further than a few hints and suggestions relative to the physical status, the management and treatment of the sick child as we find him in his home of comfort or poverty.

Perhaps I may approximate the truth by stating that the disorders of childhood are referable to one or more of four causes, and this proposition suggests the following generalized heads: anatomical peculiarities, excitability, morbific influences, and heredity, of which in their turn I will offer a few cursory statements.

On inspecting a fœtus at full term, we are struck by what appears to be a singular disproportion in the development of the body: the head is relatively much too large, the abdomen protruding and pendulous, the hips narrow, and the legs much under size, looking as though they were shriveled. Without attempting a detailed in-

*Read before the Lycoming County (Pa.) Medical Society.

quiry into the causes of these peculiarities, it may be stated that the arrangement of the prenatal circulation of the blood is amply sufficient to account for them.

The internal anatomy of the infant also differs considerably from that of the adult, the liver being exceedingly large and vascular, and well calculated for its active work of assimilation, which in the child is so much in excess of waste. The bile, notwithstanding this redundancy and vascularity of the liver is secreted in minimum quantity, as shown by the color of the stools, compared to that of after years. I take it that this may account, at least partially, for the intestinal indigestion to which very young children are so liable. The stomach is small, rugous, and less curved, with the œsophageal opening quite near the cardiac end, and thus easily overloaded. The readiness with which infants become cyanosed, and their liability to pulmonary congestion, will find an explanation I think in the relatively small calibre of the pulmonary veins and air vesicles. The foramen ovale frequently remains unclosed for months or even years after birth; though this fact may have no significance pathologically, since after the cord is tied the blood-pressure becomes equalized on both sides of the heart; this, with the natural obliquity of the valve, causes its practical closure. However, in a highly febrile state, when the left side of the heart is goaded to unwonted activity might not this balance be for the time overcome, and a sort of regurgitation take place with each pulsation, giving rise to engorgement of the lungs, embarrassed respiration and dicrotous pulse? The blood in its passage from the right auricle to the corresponding ventricle is pumped into the lungs; thence to the left auricle to be again forced into the left ventricle. Now if by any chance the ovale is not able to withstand the pressure, a portion of the blood must of necessity flow back again from the left to the right auricle, causing a secondary contraction of that organ before the left ventricle has had time to empty itself and expand for the reception of more aerated blood. This, it seems to me, might produce the conditions named.

Other anatomical peculiarities might be noticed, which as they possess little or no importance in diagnostic pathology their description would only prolong this paper unnecessarily.

We come next to consider nervous influence. The nervous excitability of the young child is so intimately connected with all pathological states, either immediately by direct action, or secondarily by reflex involvements, that it becomes an important matter for consideration. This excitability under conditions of perfect health, while poised as it were upon a balance of exquisite sensibility, comprises the stimulus which acts upon and gives tone and function to the peculiar organ of which it is a part.

The brain and spinal cord are acknowledged to be the centres of motion and will, and from them proceed all the nerves of the body, through which the electric current of sympathy and association is conducted to every part of the body. It may be stated in a general way that nerve-fiber is either motor or sensory; of the former we have voluntary and involuntary motion; of the latter, sensation and intelligence.

When we remember the anatomical distribution of the nerves, we observe how they interlock and communicate directly or indirectly with each other, and form, as it were, one universal chain of sympathy, giving unison of action throughout.

It may be further stated that each of these systems of nerves requires its own peculiar stimuli; and that the irritation or excitement produced is in proportion to the degree to which it is applied, the length of time kept up, and the state of susceptibility at the time in the organ or organs.

By excitability, then, I mean that state of an organ which causes it to respond to impressions extraneous to it. These impressions are either normal or abnormal; of the latter we have the action of disease germs, of a foreign body, as worms, or indigestible food, of violent passion, of fear and apprehension, etc., etc., showing the exercise of mental as well as physical irritants.

Healthful stimuli, on the other hand, produce their effects in the normal development of the mind and body, not so suddenly, but just as surely. This normal excitability is increased by even moderate morbid impressions when sufficiently long-continued, and thus one organ perverted from its natural function reacts upon others until finally the whole system becomes perturbed, and then we have fever, rapid pulse, and other systemic disturbances, indicating that disease is present.

Among the predisposing causes of disease in young children, aside from what has already been said, may be mentioned in passing the delicacy and laxity of the muscular fibre, as shown by the tendency to prolapsus ani; the fineness and softness of the skin and the mucous membranes rendering these organs so favorable to absorption; the easily-disturbed peristalsis of the bowels; improper food; malformation, etc., etc.

Directly upon leaving the hands of the accoucheur, the new-born child has entered a gauntlet of many dangers. It may be but a few hours after birth that he experiences his first agony in the form of a colic.

I think it is the duty of the physician to have a watchful care over the very first handling, washing, and dressing of the infant; much of his comfort or misery is due to his proper or improper dressing.

The nurse should receive the infant in a very soft piece of flannel, carefully warmed, and proceed at once to wash it; before applying the water. it should be thoroughly anointed with melted vaseline; this bland, soothing material is well calculated for the purpose, mixing easily with the caseous substance on the head and in the folds and flexures of the body, and is afterward readily removed by a neutral soap, leaving the skin soft and not liable to become chafed.

After the washing, the physician himself should dress the cord-stump, for to be rightly done it is no unimportant matter. A soft linen or muslin roller, a little wider than the length of the stump, some mutton tallow and a string are all that are needed. The nurse holding up the cord by the end, the tallow is applied to the navel, and then the roller is carried several times around it and secured with the string. As to the bandage almost universally applied to the little sensitive, compressible body, it cannot, in my opinion, be too severely denounced. It seems quite reasonable to suppose that it prevents peristaltic action of the bowels, compresses the liver, and obstructs circulation through it, and in this way is responsible for much of the colic so common to babies a few hours after birth.

It is a very common practice, likewise, to pin up the dress and petticoat waists much too tightly; this, for the very reason above stated, should not be permitted; a loosely-fitting, very soft flannel or Canton-flannel shirt, a diaper of the same material, a petticoat without constricting bands, are the rational wardrobe for the infant that has just laid aside one of such surpassing softness and flexibility as the amnion and its fluid contents.

Among the many departures from a normal state, to which very young children are liable, none are so distressing or so frightfully menace the life of the little sufferer as *convulsions*. Children of a highly nervous organization are the most likely to suffer.

It is needless to say that these terrific manifestations are generally symptomatic of the operation of some irritant, whereby the powers of the constitution become so impaired that the nervous system is no longer able to resist the strain and an explosion occurs. Sometimes, however, they are induced by sudden shock; in such cases the sensorium is the primary seat of the trouble.

Previously to the spasm, if the condition of the child has been closely watched, there will generally be found considerable derangement of the stomach and bowels; the countenance will show an unnatural expression; there will be, from time to time, a momentary distortion of the features; he will give evidence of pain, clench his fists, and throw his feet about. A peculiar, contracted appearance of the nostrils may be noticed about this time in many instances.

(*To be continued.*)

INEBRIETY AMONG RAILROAD ENGINEERS.

BY T. D. CROTHERS, M. D.,
Of Hartford, Conn.

As a class, railroad engineers in active service are exceptionally temperate men. The daily performance of their duty requires a clear brain and steady nerve, which is very soon broken up by any use of alcohol.

The nerve tension to which they are subjected in active work produces, after a time, many and profound nerve disorders. One of the hints of breaking down in this class is excessive caution and timidity. Often men who have had an accident and escaped without any external injury, will soon exhibit signs of mental shock, in what is called loss of nerve, or childish caution. Their trains will always be late, they will "slow-down" and slacken speed from no reason except some internal fears, and have to be changed to other work. Insomnia and dyspepsia are also common signs of exhaustion. After the day's run, they will be unable to sleep or properly digest food, and alcohol in some form will be found to give relief. This will soon merge into inebriety, and the drinking will be confined to the hours after the work is over. During the day they drink nothing, except perhaps beer, and that in great moderation; but when night comes, they use spirits to excess again. After a time such men will show marks of failure in excessive caution or recklessness, and be very irregular in their management of the engine. They will have heated journals and broken engines beyond the average experience.

These and many other indications soon render them unfit for the work. It is the opinion of a

competent authority, that an engineer who begins to drink will be, as a rule, obliged to give up work in two years from general incompetency, although his use of spirits may be at home and largely concealed, and in what is called general moderation. A fact has recently come to my notice with its explanation that is of unusual interest. On a through line running out from New York it has been observed that nearly all the engineers who were changed and discharged for drinking were on the night trains, and were considered the most competent. The conclusion was that men on these night runs were more likely to drink, and the individual opinions of railroad managers agree on this point.

The following is the opinion of a practical engineer, which is so literal and full of psychological suggestion that it is given in full:

"You see, in the night time, an engineer's eyes, thoughts, and all, are confined to a very small space; it's nearly or quite dark inside the cab, and if his engine is working all right, carryin' her water good, lots of steam, and the fireman wide awake and lively, that engineer don't have much to do with his eyes, only to look out ahead over the little space made bright by the headlight, and his thoughts are naturally confined to what his eyes take in. In the day-time it's different; he can look around and see lots that's goin' on. He notices that this field of taters looks good, and wonders if his little patch at home will turn out as well; he sees a fellow fishin' and remembers the last mess of trout he caught in the Shohola; he sees a woman and a baby in the little white house near the big curve, and his thoughts fly back to his home and to his wife and children, and he wonders what they are doin' just now. All this he can take in, and be tendin' to business strictly; but in the nighttime all is changed, and his vision and thoughts, as I said, are confined to the small spot made visible and distinct by the head-light, and his ideas naturally follow the rails. He remembers that the culvert just ahead is the very spot that was washed out last spring, and nothing left under the ties and rails for ten or fifteen feet; true, his engine jumped the chasm, and only five cars loaded with express matter and baggage, went down, and were smashed and piled on top of each other; but it might have been the ten cars of emigrants that were coupled in the rear, and it isn't pleasant to think what might have been. Just around the curve is the place his engine struck a draw-head some careless man left lying the track; his engine only turned over on her side, and fortunately the air-brakes had so stopped the train that no further damage was done; but he shudders as he recalls the sensation he experienced while the engine was turning over and crushing its mad way through the ties, and it isn't pleasant to think of. He flies over a huge embankment at a pace of forty miles an hour, and thinks of the feelings that were his on a certain trip last winter, when a side-rod came crashing through the side of the cab while passing over this same embankment. In the cut just ahead is where on the last trip a watchman, intent on watching a train on the opposite track, had forgotten the express which was due, and the horror and agony depicted on his face as the pilot threw him high in the air will never be forgotten, neither will his mangled and stained body, picked up and cared for as soon as the train could be stopped. And so on every mile of the road something of the kind is brought to mind as his thoughts follow the circle of light ahead, which flashes and changes constantly, now shining on a bridge, now showing an embankment, flashing its rays now on a house, now through trees and foliage; and if the man is easily bothered or worried, he gets very nervous indeed, and wishes he was at the end of his trip—anywhere off the rail.

"Why, I have known men to give up the best train on the road, and big pay, because they had to run in the night time, and take trains that were harder to run and poorer pay, simply because the latter ran in daylight. Yes, engineers do sometimes get frightened and lose nerve; and it is not to be wondered at when we think of his standing one hand on the throttle and his other on the reverse lever, with his thoughts going back to incident and incident of his busy hazardous life, on each curve and straight line of the road as revealed by the head-light of the engine."

Here is clearly outlined that fact so often seen in all circles of life of breaking down from nervous strain, where the mind has no chance to obtain relief. It is not the strain of the work alone, but the inability to get rest from other thoughts and impressions.

No wonder neurasthenia, nerve and brain exhaustion will follow, and alcohol will be found a most seductive narcotic. A most practical fact should never be forgotten by physicians who are called to treat railroad engineers, that is, never to give any form of alcohol as a medicine. Railroad officials are beginning to recognize the especial danger on these night runs, and change the train gangs often to day work.

It seems to be apparent from many facts, that

inebriety among railroad engineers is very precipitate and fatal.

A degree of degeneration is present that makes recovery difficult.

In three cases of this class I have seen, paralysis was present in each one. The use of alcohol had been confined to a very short time before they came under observation.

My object in this note is to call the attention of physicians and surgeons who are called to treat this class to the nature and character of inebriety seen among them. Also to ascertain if men who work on night trains are more likely to be inebriates than others who work in the day? How far the nature and character of engineers' work favor or retard certain diseases of the brain and nervous system?

PHENOL-CAMPHOR.

BY THEODORE SCHAEFER, M. D.,
Of Beecher, Illinois.

The writer noticed (in December, 1882,) the important fact that, when the common or Japan camphor and crystallized carbolic acid are mixed together and subjected to heat, a colorless liquid would be the result. The only reference he finds so far with regard to this reaction occurs in the very excellent and valuable scientific publication of Dr. E. R. Squibb, "Ephemeris of Materia Medica," etc., on page 673, vol. ii., No. 5, where a brief allusion appears under the appellation of "Compound Alum Powder." Dr. E. R. Squibb, however, in a letter to the writer, states that he has "several times before heard of this reaction between phenol and camphor."

Phenol-camphor is best obtained by heating crystallized carbolic acid until it melts, and then gradually adding camphor; a clear liquid is obtained, which is characteristic on account of its permanency. In preparing this substance, the writer uses equal parts of camphor and of carbolic acid. It remains liquid for an indefinite time, and does not solidify on being subjected to the low temperature of a frigorific mixture of snow and sodium chloride. Phenol-camphor ($C_8H_{11}O$ [?]) is a colorless, refractive liquid, possessing the fragrant odor of camphor, entirely extinguishing the one of carbolic acid, and has a sweetish camphoric, but biting taste, not as caustic as that of carbolic acid, somewhat benumbing the tongue. It is soluble in alcohol, ether, chloroform, and ethereal oils, but is insoluble in glycerine and water, being heavier than the latter. I have not had occasion to determine the boiling-point and the specific gravity of phenol-camphor. When ignited, it burns with a smoky flame. I have reason to believe that this compound is a chemical substance. Prof. Ira Remsen, of Baltimore, Md., in a letter to the writer, states that "I think it not improbable that the substance you speak of may be a chemical compound."

I have used phenol-camphor as a local anæsthetic in odontalgia, introducing it on cotton into the cavity of a carious tooth, with good success; and can speak of it favorably as a local anæsthetic in the ingrowing of the toe-nails.* This substance can be likewise used as an antiseptic. It mixes well with paraffine, cosmoline, and many oils. In impregnating cotton gauze (antiseptic gauze) phenol-camphor may be used as a substitute for carbolic acid. Phenol-camphor is less irritating, less caustic, than carbolic acid, and has the advantage of possessing a pleasant odor.

HOSPITAL REPORTS.

LECTURES ON INSANITY.*

Delivered at the University of Pennsylvania,

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by WILLIAM H. MORRISON, M. D.

LECTURE I.

Introductory Remarks—Definition—Classification.

GENTLEMEN: The first American course of lectures on insanity was delivered in this University by the celebrated Dr. Benjamin Rush, about the close of the last century. The same great man was the author of the first systematic treatise on mental diseases published in America. This work, issued in 1812, and entitled "Medical Inquiries and Observations on Diseases of the Mind," was in many respects in advance of its times, and abounded in striking illustrations drawn both from literature and experience.

Until 1883, strange to say, it was the only systematic treatise on insanity ever published in this country. Dr. Isaac Ray, it is true, was the author of three valuable works on medico-psychological subjects, namely, "Mental Hygiene," the "Medical Jurisprudence of Insanity," and a volume of "Contributions to Mental Pathology," but neither of these books was a general treatise on insanity.

*I have used it, in combination, in certain cutaneous eruptions due to cryptogamic cause.

*These lectures, which will be continued at intervals during the year, are placed among "Hospital Reports," because most of them will contain records of cases discussed before the class. The first two lectures are mainly didactic.

In 1883 three American text-books appeared, those of Hammond*, Spitzka†, and Mann‡. I am frequently asked by students as to recent works on insanity, and therefore make these remarks by way of introductory. A new English work of much merit has also just appeared, a volume of clinical lectures, by Dr. T. S. Clouston‖, of the Royal Edinburgh Asylum for the Insane.

Of comparatively recent German text-books, that of Krafft-Ebing§ is preëminent. It has been the fount of inspiration for much of the work of American writers on psychiatry. Of French contributors of late date I need only mention Luys, Billod, Bra, Voisin, and Ball, to each of whom we owe a volume worth consulting.

Insanity should be studied as are other diseases; but how can this be done, when as a rule, even those who go into asylums and hospitals as superintendents or assistants are, to use the words of Crichton-Browne¶, "unprepared by previous training to sift and classify the special phenomena that there fall under their notice, even if they had the leisure and disposition to do so. Unacquainted with the physiology of mind, they are bewildered by its morbid manifestations, and lack that knowledge of terms and those habits of thought that are essential to an accurate analysis of psychical derangements."

Through lectures and special instruction, the University of Pennsylvania is now endeavoring to provide some equipment for this work to those going out from its halls.

Your attendance upon the course of lectures to which this is the introductory is voluntary. The number present shows that the subject has intrinsic interest to the medical student. I wish, however, to repeat here what I have said on this subject an another occasion,** namely, that, attendance upon lectures on mental diseases should be compulsory to medical students. Everything taught in a medical school should be compulsory, should be thoroughly taught, and should be examined upon by the teacher. Only from this method of teaching can the best results be anticipated. In a school like the medical department of the University of Pennsylvania, psychiatry should be taught regularly in the third year.

Too often students and physicians are frightened from the study of psychiatry by the difficulties, or supposed difficulties, in the way. These are not altogether unreal, but they are not as great as they are often supposed to be. The perfect alienist would, perhaps, be a great psychologist as well as a practical physician; would be able to discuss the problems of Hamilton, Spencer, and Bain, as well as to go into court with a Ray, a Tuke, or a Spitzka; or prescribe with a Magnan, Clouston, or Rush. Much less than this, however, will be far more than will be usually required. The more you know the better, but it is only imperative that you grasp that portion of the field of psychology which is directly connected with the physiological studies and practical work of the profession of medicine—to quote Clouston, you can limit yourselves to "Mind, as it concerns doctors."

I shall aim to give in the concisest manner a general idea of the present status of psychiatry. After discussing briefly the definition of insanity, the methods of classification, and a few points in general symptomatology, the different forms of insanity will be taken up in order, and each will be considered after a very simple plan, namely: (1) the definition; (2) the chief symptoms; (3) illustrations; (4) diagnosis, prognosis, and treatment; (5) important medico-legal points when they arise.

Cases will be shown to you during our visits to the hospitals,* and will be discussed in greater or less detail, as circumstances permit. Occasionally an entire lecture will be devoted to a prominent Philadelphia medico-legal case.

Our subject is *mental diseases* or *insanity*. What is insanity? This question, like so many others, is more easily asked than answered. Definitions at best are generalities, usually vulnerable at more than one point. No definition of a subject so broad, so shifting, and so intricate as insanity can be free from objection. Dr. Savage† says with force that "we can no more define insanity than we can, by definition, give an impression of a rainbow or a landscape;" and the best German writers on psychiatry, as noted by Spitzka, do not attempt to give a definition of insanity at all.

"As Echo replied to the Painter in Ansonius, 'If you must needs paint me, paint a voice; if you will describe it, describe a fantastical conceit, a corrupt imagination, vain thoughts and different—which who can do? The five and twenty letters make no more variety of words in diverse languages, than it produces diversity of symptoms in several persons.' "‡

Why need we disturb ourselves to define insanity? Certainly cases of insanity can be both diagnosticated and treated by one who has not at his tongue's end some smoothly-sounding definition. One, and perhaps the main reason why it is well to have some definition at command is that everyone who has to deal with cases of insanity is liable to be called into court in the capacity of a witness. As a rule, not without exceptions, however, juries, lawyers, and judges, have little or no practical knowledge of insanity. A definition at best is but a generality, and those who know the least about a subject are inclined to lay most

‡Burton on Melancholy, quoted in Bucknill & Tuke's Psychological Medicine.

stress upon generalities. Hence it is that so much is made of definitions of insanity in courts of law.

A carefully prepared definition of insanity might be made to do genuine service in legal cases if the object in calling for it was really to get at the truth, and not to confound a witness if possible by a quibble about words and phrases.

It is advisable to have ready for use a definition that conveys an easily-grasped meaning, and one in terms that can be understood by a layman. Do not be too anxious to invent a definition, but rather, if you find one that seems to answer, appropriate it, with proper acknowledgments, of course. Whether the definition is your own or somebody else's, you may be sure it will have imperfections and shortcomings.

One calls insanity "a fever of the mind;" another, "a lesion in the association of ideas;" a third, "a loss of the faculty of volition."

Seguin* has defined insanity as "a disordered manifestation of cerebral activity." Cruse,† in a definition applauded by Hammond, speaks of it as "a psychic manifestation of brain disease."

Combe's definition, which was used with slight modification by several experts in the Guiteau trial, is as follows: "A prolonged departure, and without an adequate external cause, from the state of feeling and modes of thinking usual to the individual who is in health; also, a morbid action in one, in several, or in the whole of the cerebral organs, and, as its necessary consequence, functional derangement in one, in several, or in the whole of the mental faculties which these organs subserve."

Dr. John P. Gray's‡ definition, given during the Guiteau trial, was that "insanity is a disease of the brain in which there is an association of mental disturbance, a change in the individual, a departure from himself, from his own ordinary standard of mental action, a change in his way of feeling, and acting, and thinking."

Dr. J. G. Kiernan‖ says, "Insanity is a disease of the brain which perverts the mental relation of a patient to his surroundings, or to what from his birth, education, or circumstances should be such relations."

Spitzka's definition,§ scientific and striking, but too ponderous for ordinary use, is as follows:

"Insanity is either the inability of the individual to correctly register impressions and experiences in sufficient number to serve as rational guides to rational behavior, in consonance with the individual's age, time, and circumstance, or, such impressions and experiences being correctly accumulated in sufficient number, a failure to coordinate them, and thereon form logical conclusions; or any other gross mental incongruity with the individual's surroundings in the shape of subjective manifestations of cerebral disease or defect, excluding the phenomena of sleep, trance, somnambulism, the ordinary manifestations of neuroses, such as epilepsy and hysteria, of febrile delirium, coma, acute intoxication, and ordinary and immediate results of nervous shock and injury."

Dr. Hammond* defines insanity as "a manifestation of disease of the brain, characterized by a general or partial derangement of one or more faculties of the mind, and in which, while consciousness is not abolished, mental freedom is weakened, perverted, or destroyed."

These are a few out of a large collection of definitions in my possession. None of this collection are entirely satisfactory, although many are ingenious and some very good.

I would define insanity as a disease or condition of the brain, in which, without loss of consciousness, the integrity of the mind is impaired or destroyed.

For legal purposes in homicide cases, a good definition could be made by adding to the above that insanity is a disease so affecting the mind as to prevent the individual either from knowing the nature of the act done by him, from knowing that it is forbidden by law, from knowing that it is morally wrong, or from controlling his own conduct.

These criteria of responsibility are from a bill drafted by Sir J. Fitzjames Stephens, and introduced into the House of Commons in 1874.

Owing to the imperfect state of the science of psychiatry, a satisfactory classification of the subject of insanity is impossible. Almost every author attempts a new method of classification, or engrafts upon an old plan some new ideas. Various principles are at the bases of these attempts.

I will not attempt a new classification, but will simply consider successively those forms of insanity which are recognized by our best recent authorities—Krafft-Ebing, Spitzka, Hammond, Clouston, and others. Without adopting any special plan of arrangement, psychological, symptomatological, etiological, etc., I shall simply give a working list of insanities met with in practice, as follows:"

1. Mania.
2. Melancholia.
3. Monomania.
4. Circular insanity.
5. Periodical insanity.
6. Katatonia.
7. Stuporous insanity.
8. Confusional insanity.
9. Hebephrenia.
10. Senile dementia.
11. Primary dementia.
12. Secondary dementia.
13. Paretic dementia.
14. Insanity from coarse brain disease.
15. Syphilitic insanity.
16. Epileptic insanity.
17. Hysterical insanity.
18. Alcoholic insanity.
19. Puerperal insanity.
20. Idiocy and imbecility.
21. Cretinism.

Under these heads are included forms of insanity which have prominent and distinctive psychical features. They are forms, each of which includes a considerable number of cases, and each

§ Op. cit.

† Op. cit.

of which has been well studied and carefully differentiated. In a journey through a large asylum they could be picked out and separated into groups with but little difficulty. The list constitutes a practical summary of the most typical forms of mental disorder.

I have given only the general forms. Some of these, as mania, melancholia, monomania, epileptic insanity, alcoholic insanity, etc., have well-marked subdivisions, which will be considered when I come to speak in detail of each kind of insanity.

Some of the terms used are etiological—thus "syphilitic," "epileptic," "hysterical," "alcoholic," and "puerperal" insanities are enumerated. These varieties, however, have—or with our present knowledge appear to have—special psychical and other manifestations, which justify their erection into great groups.

By fully applying the etiological and diathetic method, the varieties of insanity might be almost indefinitely extended. The following is a long, but not complete, list of the constitutional and complicating insanities, which have been given a local habitation and a name in text-books and classifications, and will be briefly considered during the course:

1. Traumatic Insanity.
2. Pellagrous Insanity.
3. Lactational Insanity.
4. Insanity of Pregnancy.
5. Masturbational Insanity.
6. Post-Connubial Insanity.
7. Climacteric Insanity.
8. Post-Febrile Insanity.
9. Phthisical Insanity.
10. Gouty Insanity.
11. Rheumatic Insanity.
12. Choreic Insanity.
13. Insanity of Bright's Disease.
14. Diabetic Insanity.
15. The Insanity of Oxaluria and Phosphaturia.
16. Insanity of Heart Disease.
17. Insanity of Addison's Disease.
18. Insanity of Exophthalmic Goitre.
19. Insanity of Myxœdema.
20. Insanity from Lead Poisoning.
21. Insanity from Special Drugs—Opium, Absinthe, etc.
22. Delirium of Young Children.

Medical Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

(*Concluded from page* 142.)

In his paper before the International Congress of London (vol. iii., 640), Dr. Raynor supported the following conclusions:

1. Protracted gouty toxæmia, when not very intense, usually results in sensory hallucinations or melancholia.

2. Sudden and intense toxæmia results in mania or epilepsy.

3. Intense and protracted toxæmia usually results in general paralysis.

4 If there be a tendency to vascular degeneration from plumbism, alcoholism, etc., varying degrees of dementia are produced.

In the discussion which followed the reading of Dr. Raynor's paper, Drs. Savage and Crichton Browne, of London, both expressed the belief that gout does cause insanity, the latter, however, qualifying by the statement—only where there is hereditary predisposition to insanity.

Further proof of the connection between gout and insanity may be found in the Paris Thesis of M. Belliard (1882, No. 269), in which are detailed various cases.

The facts that in Mrs. L. the attack was at the time when an explosion of gout was to be expected, that in all her previous attacks mental depression was a distinct feature, that her urine was loaded with lithates, although she was taking very little food, and that there was widespread exquisite tenderness and soreness to movement with febrile reaction, appear to estabish a gouty etiology. The contraction of the lumen of the basilar arteries was seemingly sufficient to check the freedom of blood supply to the brain. Brain anæmia certainly existed, as was proven by the autopsy, and no doubt it aided in causing mental weakness.

It is certainly worthy of remark as confirmatory of the generalizations made by Dr. Raynor that the type of mental disturbance exactly corresponded with his conclusions. There was a pronounced tendency to vascular degenerations, and the mental disturbance partook of the nature of dementia.

Passing from the discussion of the etiology of the case, we note the rapid formation of a recto-vaginal circular ulcer as most extraordinary; its occurrence was entirely spontaneous. It seems to resemble in its nervous pathology the rapid eschars which sometimes form upon the buttock and extremities in severe myelitis, or perhaps even more closely the so-called perforating ulcer of the foot.

The temperature sheet of this patient was remarkable owing to the differences between the two axillæ: although, as the autopsy showed, there was no focal brain lesion to account for such difference.

Irregularities of local temperature are well known to occur in local diseases of the brain, and the temperature in the two axillæ in the present case was first tested for diagnostic purposes. The result shows that we may have such irregularities of temperature when there is no local lesion. In a case now under my care at the Philadelphia Hospital believed to be suffering from an acute myelitis, the temperature for many days varied in the two axillæ from 0.2° F. to 1.5° F. To my mind it is evident that we need careful bilateral studies of temperatures in various diseases.

The point to which I want to direct special attention, however, is that the urine was examined various times by Dr. Tomlinson without his finding any evidence of contracted kidney, although such lesion existed. My first glance at the patient made me think that she had chronic Bright's disease, but a very careful examination of the chemical reactions, the specific gravity, and the microscopic deposits of the urine, so entirely failed to justify any suspicion that I was entirely misled in this feature of the case. I should here state

that my own examinations of the renal secretion were so entirely in accord with the statement of Dr. Tomlinson, that they were not, as they ought to have been, repeated upon various specimens of the urine. As already stated, the aspect of Mrs. L. suggested the existence of chronically contracted kidney, but there was no increased arterial tension, the heart's action whilst she was under my care being uniformly feeble. It is many years since I ceased putting confidence in the absence of albumen as being of much value in disproving the existence of contracted kidney, but I have hitherto believed that reliance could be placed upon the specific gravity of the urine. The importance of examining the specific gravity of the urine cannot be over-estimated; and the import of a persistent specific gravity of 1010 or under can scarcely be mistaken; but in addition to the case just detailed, the following is of great interest as indicating that normal urine may accompany a fatally diseased kidney.

Mrs. ——. aged fifty-eight, the mother of two healthy children, consulted me in the month of April, 1883, on account of certain spells which afflicted her. The history she and her daughter gave was in brief as follows: The attacks first began in 1876, about the time she ceased menstruating, and had continued ever since; they always came on when the stomach was empty and were sure to happen if at any time during the day she was more than three hours without food, also if she does not get breakfast upon rising, she is sure to have a seizure. Excessive fatigue increases the tendency to attacks. The spell commences with extreme pallor of face and dark rings under her eyes; if walking, her gait becomes very slow; if talking, her speech slackens and then ceases; she looks around in a dazed, bewildered manner, but does not fall, and is not convulsed at all; she does not become completely unconscious, but does not know where she is or what is going on about her; if a mouthful or two of food be forced down her, she arouses immediately, but has no memory of what has occurred during the spell. A careful examination of Mrs. —— resulted in complete negations so far as organic disease was concerned. The urine was normal; there was no failure of mental power, choked disk, palsy, headache, or other local symptom discoverable, and I finally settled down to the diagnosis of gastric vertigo. Under appropriate treatment the patient improved, and I saw her at my office for the last time June 4, 1883.

In April, 1884, I was hastily summoned to her bedside and found her comatose, with a history of distinct convulsions which were said to have been diagnosed as hysterical by a neighboring practitioner, who, I was also told, after examination of the urine, had stated positively there was no disease of the kidneys. On post-mortem examination, the brain was found normal, but the kidneys presented the gross appearances of advanced contracted kidney; and careful microscopical examination by Dr. G. A. Piersoll proved that the condition of the organ was as it appeared.

A second case bearing upon the matter in hand is that of—

Mrs. I. W. T., a large, stout woman who came my office early last March on account of failing eyesight. Her appearance and description of her symptoms led me to think that she had albuminuric retinitis, but without any examination I sent her to Dr. Harlan, who reported that she had unmistakable albuminuric retinitis, and that no local treatment would be of service.

Her urine had, the day of her return to me, a specific gravity of 1020, and with the nitric acid gravity test yielded no cloud, or one so faint that I could not be sure that it existed, and noted, "believed to have a trace of albumen." According to her estimate, she was passing two and one-quarter pints a day.

April 3d. She passed three and a half pints, having a specific gravity of 1010, and totally free from albumen.

21st. Urine three pints, specific gravity 1015; no albumen.

The symptom of increased arterial pressure and cardiac hypertrophy, upon the diagnostic value of which stress has been laid, afforded in the group of cases here narrated no aid. The patients were all large, stout, middle-aged, married women, with full busts, making the recognition of a slight degree of hypertrophy exceedingly difficult, and the circulation in the two more serious cases was certainly enfeebled.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Some Cases of Disturbances of the Normal Vaso-Motor Tonus,

Was the title of a paper read by Dr. Edward T. Bruen, as follows:

My object in this paper is to relate some examples of general anasarca due to vaso-motor lesion, and also some instances of acute pulmonary congestion and œdema due to the same cause. The cases given in detail have been selected because in each instance an autopsy was made.

In December, 1879, I reported before the Philadelphia County Medical Society some cases of general anasarca in subjects of malarial poisoning without lesion of of the heart, kidneys, liver, or blood. The absence of anæmia or special corpuscular changes in the blood, was established by the use of the hæmacytometer. The dropsy was attributed to depression of the vaso-motor tonus. The line of argument on which the diagnosis was established was by exclusion of all other causes of dropsy, and by an analysis of the experimental evidence bearing upon this topic.

Quoting from that paper: Experiments bearing on this subject were made in 1680 by Lower, who tied the venæ cavæ and found that œdema followed in the lower extremities, which he ascribed to the diminished absorption of intercellular fluid owing to venous congestion. Ranvier has proved that œdema depends not only upon diminished absorption, but also upon increased exudation from the vessels. To prove this he first tied the venæ cavæ in the abdomen of the dog, and found that œdema did not appear, for although there was undoubtedly repletion of the arterial system, yet the lymphatics were able to absorb the exudation without any assistance from the veins, and therefore no accumulation of fluid took place.

But if the sciatic nerve was cut upon on one side, intense œdema occurred in the correspond-

ing limb. Venous congestion was undoubtedly present in both legs for the venæ cavæ had been ligated, but in one the nervous influence proceeding to the arteries through the sciatic nerve, kept them contracted, and prevented the exudation of more fluid than the lymphatics could absorb.

In the leg in which the nerve had been paralyzed by division, the vessels dilated, the limb became rosy and warm, and so much fluid was poured out that the lymphatics alone could not absorb it without the aid of the veins.

Ranvier further proved that this was due to the paralysis, not of motor, but of vaso-motor nerve-fibres which are contained in the sciatic. Because, after cutting in different animals motor and vaso-motor nerves in the lumbar region before they had united to form the sciatic nerve trunk, when the motor fibres were divided as they issue from the lumbar vertebræ before uniting with the sympathetic fibres, complete paralysis of the legs was produced, and no œdema occurred; but if, on the other hand, he divided the sympathetic fibres passing to the sacral plexus there was no motor paralysis, and œdema occurred.

We can therefore conclude that paralysis of the vaso-motor nerve is sometimes an important factor in the production of anasarca. But the production of anasarca in the instances already mentioned (viz., those in which there is no mechanical explanation or lesion of the blood tissue) is probably also due in part to suspension of the functions of the skin. The function of the skin is not alone dependent on the blood-supply of the skin, but is also under the control of the innervation of the nerves supplying the cutaneous glands.

Dr. Foster states that the skin of dogs and cats can be made to act, and sweating produced by stimulation of the sciatic nerve after clamping the aorta, and the same result he has obtained in the leg of the frog by stimulating the sciatic nerve after amputating the leg. The existence of secretory nerves and their special influence over the secretions of the skin, has also been affirmatively investigated by Dr. Isaac Ott, and G. B. Wood Field, in a series of original experiments. Their article is entitled "Sweat Centres, the Effect of Muscarin and Atropin on them."

To sum up: in the anasarca following malaria, under the conditions already stated, we can as readily understand the action of the malarial poison upon the vaso-motor and spinal centres, as we can trace the impaired nutrition of those suffering from repeated malarial seizures, to a condition of the nervous system universally credited to the unfavorable action of the malarial poison upon it.

Since 1879 a number of cases of general anasarca have come under my notice, which I have ascribed to sudden depression of vaso-motor tonus (usually through malarial influences), but I have not had an opportunity of making an autopsy on any one of them. The following case of acute general anasarca, however, occurred under my observation in Dr. R. G. Curtin's ward in the Philadelphia Hospital, and through his courtesy I have privilege of reporting it:

Case 1. A well-nourished man, æt. 38, was admitted to the hospital October 15. Prior to October 8, he had been a healthy man, a driver on the street-car by avocation. He had always been used to drinking spirits freely while on duty, to counteract the effects of exposure; but he had not been often drunk. However, after an unusual indulgence, he was seized suddenly with œdema of the genitals, which, within twenty-four hours, was followed by anasarca affecting the cellular tissues of the abdomen and loins, and finally the limbs became swollen. Associated with the œdema was rapid action of the heart with shortness of breath. On the day of his examination in the hospital, the tissues already named were very much swollen, and there was the most profound functional disturbance of the circulation. The heart's action was over 220, as counted by both Dr. Curtin and myself. Withal, the facial appearance of the patient was that of robust health, and the cheeks bore a ruddy hue. The systole of the ventricle seemed normal in force, producing a distinct first sound, and a good impulse could be felt. The physical examination of the lungs revealed only the signs of moderate passive congestion; the liver was normal, and the condition of the urine entirely physiological, as shown by repeated tests. After treatment for two weeks a marked improvement was secured, the pulse fell to 120, the anasarca nearly disappeared, and entire convalescence was expected. One morning on rising from the bed the patient suddenly gasped for breath, and fell over on the bed, dead from asystole of the heart. A careful post-mortem revealed slight hypertrophy with dilatation of the heart, which weighed fourteen ounces. There was also slight atheroma of the aorta. The lungs were somewhat congested; brain, on macroscopic examination, normal; and the kidneys natural. The liver was slightly cirrhotic, weighing sixty-one ounces. The above insignificant modifications in the tissues were credited to chronic effects of alcohol, and the case appears to me to illustrate vaso-motor dropsy, and to sustain the view that various influences as well as malarial are capable of producing vaso-motor paresis with anasarca.

When we review the history of cases of sudden pulmonary congestion and œdema due to or associated with vaso-motor weakness, we find the best illustration in acute œdema of the lungs in subjects of chronic alcoholism. In these cases œdema may develop in a few hours, attributable to the effect of alcohol on the vaso-motor system.

Alcoholic pulmonary œdema differs from the secondary hydræmic œdema of Bright's disease, scorbutus, purpura, anæmia, etc.; because alcoholic subjects are not always anæmic. Alcoholic pulmonary œdema may exist independently of organic heart disease, or inflammatory processes in the lungs such as pneumonia, capillary bronchitis, miliary tuberculosis, etc. The cases I shall presently report represent pulmonary congestion and œdema from vaso-motor paresis analogous to cases of alcoholic pulmonary œdema, and similar to those cases which occur from deficient vascular tonus from pressure on the vagus or the pulmonary plexus.

Similar forms of œdema occur in acute general diseases, such as typhoid, typhus, and scarlet fevers associated with feeble heart action. Pulmonary œdema from lowered vaso-motor tonus

occurs in the aged or feeble, and is associated with catarrhal swelling of the bronchial mucous membrane.

The following cases of pulmonary congestion with œdema, however, occurred suddenly and in young, previously healthy, persons, who were not directly subject to any of the above predisposing causes.

Case 2. Emma E., æt. 38. Admitted to the Philadelphia Hospital October 9. Had been in good health up to within two or three days previous to admission. On examination, she complained of dyspnœa, and fine crepitant rales were heard all over the lower lobe of the left lung. On the 11th, the same variety of rales were heard over the lower right lobe, and had disappeared on the left side; no dullness over either side of the chest, and respiratory murmur slightly harsh, but normal. No evidence of disease of heart, kidneys, or blood, nor of inflammatory disease of the lungs. Temperature 98° F. These physical signs continued until the 14th, unchanged except that the rales grew more moist, and affected both lower lobes. On the night of the 14th, she was suddenly seized with intense dyspnœa and very quickly became livid and unconscious. Physical examination revealed intense pulmonary congestion and œdema.

The treatment instituted was hypodermic injections of atropia, at first $\frac{1}{100}$ of a gr. and then $\frac{1}{50}$ of a gr., three injections being given; also two injections of $\frac{1}{50}$ gr. strychnia inside of six hours; together with these measures cardiac stimulants, digitalis, alcohol, and ammonia were freely used, with dry and wet cupping. These measures produced great relief, and in the course of twelve hours the patient was easier and conscious. The treatment by atropia and strychnia hypodermically injected, was continued by Dr. Jenkins t. d. during the 15th, and the cardiac stimulation several days. The congestion almost entirely disappeared, and we cherished the hope of an entire convalescence, when on the 19th she had a chill, the temperature rose to 103°, and within two days pneumonic consolidation of the right upper lobe ensued, which proved fatal. An autopsy revealed no lesions save the apex pneumonia in the second stage.

The Management of the Third Stage of Labor.

Dr. Wm. J. Smyly read this paper before the last meeting of the British Medical Association.

The subject is one of the greatest importance both as regards the mother and her child, and it cannot be doubted by any one who has seen much midwifery practice, or who has read the cases published in the medical periodicals, that, even at the present time, numbers of lives are lost through mismanagement of this stage of labor.

This subject divides itself into two parts: first, as regards the mother; and secondly, as regards the child. I shall confine myself to the former of these, namely, What is the best method of conducting the third stage of labor so as to insure the safety of the mother? And here I would state, as the great fundamental truth, the aphorism of Professor Credé, that, "the uterus itself should expel the afterbirth, and the sooner it does it, after the expulsion of the fœtus, the better. If it do not do so, it must be made to, otherwise it may be too late, and the dangers of retained placenta come into force." If this be true, and I cannot imagine any grounds for thinking that it is not so, it altogether eliminates such practices as pulling upon the cord; attempting to express the placenta from a relaxed uterus; "the imitation of the pains when absent," as recommended in one of our most popular text-books; or the introduction of the hand into the uterus, unless in cases of absolute necessity. Of all these methods, perhaps the most disastrous is that of pulling on the cord, resulting, as it has done, in its avulsion, entire or partial, with retention of the placenta and membranes; irregular and inefficient contraction; and partial or complete inversion of the uterus, and violent hemorrhage. All these dangers have been so frequently dwelt upon, that one might have hoped that by this time the practice would have been entirely abandoned; but this does not appear to be the case, and amongst a series of communications on the subject of hour-glass contraction of the uterus, which appeared this year in the *Brit. Med. Jour.*, is one by a gentleman who not only admits having pulled upon the cord, but adds that "any one else would have done the same." Neither does it seem to have occurred to him that the anomaly which he describes was the result of his own mismanagement. Such practice destroys the natural mechanism of placental delivery, and is almost invariably followed by considerable loss of blood.

If, then, the uterus is the proper agent, not only for the completion of the birth, but also for the extrusion of the after-birth, why not regard the third stage as a physiological process, and, just as in the other two, observe, unless in case of absolute necessity, a purely expectant attitude? This inactive method has been adopted in some of the Continental hospitals, and has been advocated by Drs. Ahlfeld, Teuffel, and Kabierske, the last of whom has set forth the following propositions:

"1. The natural powers of normal labor are sufficient for the perfect separation of the afterbirth, and the completion of the placental stage, and do so much better and more completely without artificial aid than with it.

"2. The expectant treatment of the placental stage is free from danger."

The first of these propositions is true, and is borne out by statistics. The method adopted in the Strasbourg clinic was, in normal cases, expectant; the state of the uterine contraction being from time to time observed, as well as the amount of the discharge; and the bladder and rectum were carefully attended to. Thus hours were often allowed to pass, without any attempt to remove the placenta, even though lying in the vagina. Out of 100 cases treated thus, the placenta was expelled in 69 within three hours. This is more rapid than the observations of others would have led us to expect, and was probably, in some measure, due to the action of the bladder and rectum; for it was usually during an effort to relieve either of these viscera that the placenta was expelled. The old wives' plan of giving the woman a pinch of snuff would be equally efficacious and more agreeable.

By this method it is alleged—and this is the strongest point in its favor—that the membranes, and especially the decidua, are much more completely separated than a more active one. Instead of being expelled as a thin, and in many places an imperfect, membrane, the decidua was found to be by far the thickest portion of the coverings of the ovum. Thus the expectant plan appears to be followed by a better separation of the decidua; but, on the other hand, it is liable to be attended by violent hemorrhages, which not only immediately imperil the patient's life, but subsequently tend to relaxation of the uterus, permitting the formation of clots within its cavity, which by decomposition might occasion putrid infection. Even Kabierske himself admits that the average amount of blood lost in his cases was greater than that recorded by others; and, though he makes light of this circumstance, there is good reason to believe that it is often sufficient to occasion alarm. It also permits irregular contraction of the uterus, and incarceration of the placenta, necessitating more frequent introduction of the hand, and thus increasing the liability to septic inoculation. Besides, the long delay is not only irksome to all concerned, but is calculated to excite and alarm the patient and her friends. The second proposition, "that the expectant treatment is free from danger," must therefore be rejected as not borne out by facts.

The relative results of the expectant and a more active method of treating the placental stage are clearly shown by the following statistics by Dr. Weir, of Copenhagen:

Cases treated.	*Expectantly.*	*Expression.*
Post-partum hemorrhage, . .	5.78 per ct.	2.3 per ct.
Manual removal of placenta,	1.33 "	0.64 "
Retention of membranes . .	1.78 "	2.3 "
Secondary hemorrhage . . .	0.77 "	0.32 "

From these statistics, it appears that the only advantage of the expectant method is that retention of the membranes is less frequent; but, in spite of this, and contrary to what might have been expected, secondary hemorrhage is more so.

The results of the expectant method should teach us to keep a constant control over the uterus, by holding it with the hand, and never allowing it to relax. This is the method which has been practiced in the Dublin Lying-in Hospital for upwards of a century, and is similar to that introduced into Germany by Prof. Credé. A good deal of controversy has arisen as to whether these two methods, namely, the Dublin method and Credé's, are the same or different. I shall, therefore, describe them separately, and afterwards compare them with each other.

The Dublin method has been followed in the Rotunda Hospital certainly since the mastership of Dr. Clarke in 1789. It was described by Dr. Dease, of Dublin, in 1783, and by Drs. Hardy and McClintock, in 1848. I shall quote their description (*Practical Observations on Midwifery*, p. 221).

"Having placed the hand on the fundus uteri, friction and slight pressure are to be made, and, if the amount of contraction thereby induced be not sufficient to repress the hemorrhage, it will be necessary to expel the placenta from the cavity of the uterus. In doing this, the organ must be grasped firmly, and pressure exerted upon it in the axis of the brim of the pelvis. If the uterus have fallen to the left side, as not uncommonly happens, it must be raised into its natural position, before commencing to exert compression upon it. It will also tend much to the success of the manipulation, if it be performed during the presence of uterine action. Indeed, we have sometimes been surprised at the ease with which the placenta was pressed off during a contraction of the uterus, while previously it had withstood our best directed efforts. These measures we have seldom found to fail in getting away the placenta, unless it be morbidly adherent."

In 1853 Professor Credé first published an account of his method. Quite unacquainted with the Dublin practice, he was led to the discovery in the following way. Being frequently called to cases of retained placenta attended with hemorrhage, he found that examining the uterus externally was often sufficient to excite so violent a contraction as to expel the placenta even outside the vulva.

So gratified was he by this unexpectedly favorable result, that he adopted a similar treatment in every case, with marked success. He recommends that as soon as possible after the birth of the fœtus, the hand should be placed over the region of the uterus, making, at first, gentle stroking movements, until it is felt as it commences to contract beneath the fingers; then, as the contraction reaches its acme, the organ is grasped in one or both hands, the fingers being spread out over it; thus its walls are squeezed together, and pressure is made towards the coccyx.

The chief point is, to seize the exact moment when the contraction is at its height. By this method, in a favorable case, the afterbirth can be expelled by a practiced hand, with the first or second after-pain. As a rule, however, it follows with the third or fourth, that is, in about five minutes. If it do not come, he waits for more pains, and acts in a similar manner with each; it seldom requires more than fifteen minutes. He specially cautions against impatience or violence in manipulation.

Each of these methods has some direct advantages. By following its contraction, the intestines are prevented from falling down in front of the uterus, and thus pressure can be made more directly upon it. By never allowing it to

relax, irregular contraction and hemorrhage are avoided, so far as is possible. Professor Spiegelberg lays great stress on the importance of this practice. "It is not," he says, "identical with Credé's method. Whilst in the latter the hand is placed upon the uterus after the birth of the child, and by powerful irritation excites it to contraction; I lay the chief stress, after the example of the Dublin Lying-in Hospital, upon the immediate general contraction of the uterus, whilst through this the separation of the placenta is brought about; and this, not the expression, is the chief point. Thus from the birth of the head, by following the uterus, and by mechanically exciting it, I make the contraction which necessarily accompanies the expulsion of the fœtus, both energetic and continuous.

Thus I often obtain rapid separation of the placenta, and prevent irregular contraction of the uterus. In Credé's method, irregular contraction may set in, unobserved, between the birth of the child and the commencement of the process; whilst by the above method this is impossible." The importance of this point is also illustrated by two cases published by Dr. Garrigues, in which violent, and in one case fatal hemorrhage occurred, before Credé's method could be practiced (*Amer. Jour. of Obstet.*, May, 1884).

In Credé's method, friction and pressure are more actively and systematically carried out than in the Dublin method, and so the expulsion of the placenta is hurried; but the liability to retention of the membranes is increased. The importance of this latter complication is at present, however, uncertain. The expulsion of the placenta from the vagina by pressure alone, without introducing the fingers into the vagina, is a decided improvement, and is the natural outcome of antiseptic teaching. That it was not appreciated by Irish obstetricians, more than one hundred years ago, is not to be wondered at, yet Dr. Garrigues has seized upon this one point to disparage altogether what he contemptuously designates the "so-called Dublin method." It is much more surprising that he should himself, according to his own confession, have practiced, until eight years ago, "the old way of pulling on the cord."

My own belief is that a mixed method, combining the advantages of the Dublin with those of Credé's method, is the best possible. The following are the most important points to attend to: Follow the contracting uterus, as it expels the child, and by pressure and friction make this contraction energetic and permanent. Never let it go, unless compelled to do so; and then always provide a substitute, the nurse, a friend, or even the patient herself. It is wrong to resign such an important function, simply to tie and divide the navel string. During a contraction, press the uterine walls together, and the entire organ towards the coccyx. When sudden flattening of the uterus shows that the placenta has been expelled from it, then by strong pressure downwards drive it out of the vagina. The placenta should not be shot out upon the bed or into a vessel held against the buttocks, since the membranes are thereby liable to be torn across, but it should be received in the hand at the vulva, and rotated so as to twist the membranes into a firm cord which is easily withdrawn, without, as a rule, leaving any portions behind. Should this accident, however, occur, I think it is less dangerous to leave them than to introduce the hand for their removal; but should they prove a cause of hemorrhage they must be taken away.

Finally, I quite agree with Dohrn, Runge, and others, that beneficial as is the active method when properly employed, just so injurious is it when unskilfully carried out. The hasty and violent expression of the placenta from an imperfectly contracted or relaxed uterus is a frequent cause of retention of the membranes and portions of placenta, as well as of violent hemorrhage and fever.

The Physiological Action of Coca and Cocaine.

Dr. Eber Caudwell thus writes in the *Brit. Med. Jour.*, January 3, 1885:

The following observations made on myself were undertaken at the suggestion of Dr. Murrell, with the view of ascertaining whether coca or its alkaloid possessed any toxic action. The first series was made with valoid of coca, a fluid extract, each part of which corresponds to an equal weight of the leaves of the coca plant. On December 9th, at 2 p. m., being busily engaged in seeing out-patients, I took two drachms in water, and experienced nothing but a little frontal headache. On the 9th, at 7 p. m., after a hard day's work, I took three drachms, and almost immediately fell into a deep sleep, which lasted four hours. On the 13th, I took five drachms at bedtime, slept for two hours, and then passed a restless night. On the 16th, I took a fluid ounce at bedtime, and was kept awake all night. There was a general feeling of well-being, with considerable mental excitement, and I was able to read steadily for many hours. On the 19th, I took two ounces at midnight, suffered severely for ten minutes from giddiness and unsteadiness of gait, and then experienced the same sensations as on the previous evening. There was renewed mental and physical activity, and I felt that any exertion could have been undertaken without difficulty.

My next observations were made with the hydrochlorate of cocaine, a supply of which was kindly placed at our disposal by Mr. E. Merck, of Darmstadt. Half a grain, taken by mouth at bed-time, produced drowsiness; a grain induced sleep, followed by persistent insomnia; two grains and a half gave rise to frontal headache, great mental excitement, and marked insomnia. Failing to produce any decided toxic effect, I took, at 7 p. m. on the 29th, a single dose of three grains. I had just come off a long railway journey, and had purposely abstained from food for nearly twenty-four hours. At first I felt decidedly sleepy, and there was slight vertigo; but these symptoms soon passed away, and, in the course of an hour, I felt perfectly fresh and well, and remained awake all night. At 10:30 on the following morning, I took five grains more, and then felt that a decided effect had been produced. In a few minutes I was so giddy I could hardly stand, and was quite unable to make any exertion. There was a slight supra-orbital headache, and a feeling of weight or sinking at the pit of the stomach. The pupils were widely dilated, and I could hardly see. My temperature was taken four times, and was found to vary from 96.7°

to 98.6°. The pulse, for a few minutes, rose to 94, but, as a rule, was not above 80. The urine passed at the time had a specific gravity of 1020, and was normal. In about two hours, the unpleasant sensations passed off, and I walked to the hospital, a distance of four miles, in something under fifty minutes. By one o'clock I was quite myself again, and was as fresh and vigorous as ever. The dilatation of the pupils continued for six hours. From these observations I conclude:

1. That coca and cocaine exert a double action, acting as cerebral sedatives in small doses, and as cerebral stimulants in large doses.

2. That cocaine, given internally, dilates the pupils.

3. That cocaine, unless in large doses, possesses no toxic action.

The Snow Cure.

From an illustrated paper, by W. George Beers, on "Canada as a Winter Resort," in the February *Century*, we quote the following: "It is by no means every delicate person who should make Canada his winter resort; but it is well known that our winters have cured chronic cases for which Colorado and Florida were alone supposed to be beneficial. Every winter numbers resort to Montreal, Quebec, Halifax, and Winnipeg for no other reason than that for which they once went to tropical climates. I know of patients who were regularly sent to Bermuda and the West Indies, and others to such winter climates as Nice, without more than temporary benefit, who were completely cured by the outdoor life of our Montreal and Quebec winters. Two years ago we had an exceptionally severe winter in Manitoba. Its severity and peculiarities were precisely the same in Dakota and Minnesota. I was *en route* from Brandon to Winnipeg, a distance of one hundred and eighty miles by rail, and was caught in a snow-blockade which lasted eight days, and kept us in a situation not likely again to occur. The storm was so severe that relief-trains could not leave Winnipeg, and a couple of us who had the long snow-shoes used on the prairies tramped to and from farm-houses a couple of miles distant for provisions for the passengers. The snow-plows were of no use, and in a desperate attempt to cut a way through the drifts, the engine jumped the track and came to grief. The train was pulled back from the *débris* by an engine in the rear, and the next morning we found ourselves separated from the wreck by deep drifts, some of them fifteen feet high. Night after night passed; the coal and wood ran short; two of the cars were abandoned by the passengers, and, to economize fuel, we were crowded into the two remaining cars. The sleeping accommodation improvised was very amusing. Fancy roosting two in a single seat, with your knees doubled up to your chin; or lying like sardines, four in a double seat; or propped on top of the back of the seats, which were turned up and brought together so as to form a sort of double deck. Shovelers had been working day and night, but there were too few of them; and at last the passengers went to work, and from 9 a. m. until 5 p. m. pitched the snow with might and main, and succeeded in clearing the track. In order to pass the obstacle of the wrecked engine, we raised old rails, got ties and laid a new side-track on the hard snow, and our cars were safely shoved forward. Shovelers from Winnipeg had succeeded, with the snow-plow, in reaching us, and we were soon on our way. The effect of this exposure upon the health of many of the passengers was remarkably good. One clergyman who had come out from England for some affection of the throat, was determined to do his share of the shoveling. He had very thin moccasins on his feet, and during the day, as there was a warm wind, they were wet through. He never expected to see England again, but that one day's work cured him effectually. Other persons suffering from throat and lung affections have not since been troubled. One would suppose the conditions were just to provoke illness, but the very reverse was the case."

Urethral Fever.

The *London Medical Times*, January 3, 1884, says that urethral fever formed the subject of Mr. Horsley's fourth lecture at the London University. He thought it impossible that this fever could be of other than neurotic origin; its rapid appearance, usually in four hours, and its supervention upon simple catheterization when no abrasion was believed to have occurred, rendered untenable the theory of a septic pathogenesis. Urethral fever he divided into two varieties, (1) an acute, "fulminating," occurring usually from catheterization, and (2) a subacute fever occasioned by internal urethrotomy. The fulminating variety occurred mostly in patients who were under treatment for the first time, and whose strictures were of recent formation. The rise of temperature in the second class was much slower, being preceded by a subnormal drop of 1°, due probably to shock. The maximum temperature was attained in 23 hours. This class of cases occurred among patients who had been the subject of stricture for several years, and had had more or less treatment preliminary to the urethrotomy, which was the immediate antecedent of the fever. In cases in which no pyrexia supervened upon treatment, Mr. Horsley found the stricture to have been always of very long standing, extensive treatment having previously been undergone. To explain the pathogenesis of urethral fever, he invoked the aid of the hypothetic heat centres in the spinal cord. The researches of Quincke, Naumyn, Wood, Heidenhain, and others, rendered it probable that such centres do exist, and are in all likelihood thermo-inhibitory in nature. In a urethra crippled by a recently-formed stricture, the nerves would be highly sensitive, and would readily respond to stimulation, and hence reflex heat changes would in such cases naturally be initiated, while in long-standing stricture the sensitive character of the urethra would be considerably impaired, a result also largely brought about by previous manipulation. The evidence was, in Mr. Horsley's opinion, altogether opposed to Sèdillot's septic theory, and lent itself readily to one which appealed to a neurotic origin. Thus chloroform, ether, morphia, quinine, which could not exert any influence upon septic absorption, controlled alike the rigors

and the pyrexia which, without their employment, ensued in surgical manipulation of the urethra. Drawing practical conclusions from his cases, Mr. Horsley found continuous gradual dilatation with internal urethrotomy to be the procedures most free from the risk of pyrexia. He advised that chloroform should be administered, the urethra dilated to No. 4 E., and internal urethrotomy then performed. No instrument should be left in the urethra, nor should one be passed for 96 hours after the operation. Morphia might be used an hour before the operation, and recourse had to quinine for the after treatment. The urine in these cases was somewhat lessened, but rapidly returned to its normal standard.

Cocaine in Dysmenorrhœa.

Dr. John Forrest, of Charleston, S. C., thus writes in the *Med. News*, January 10, 1885:

My patient has suffered for years from painful menstruation, accompanying a retroflexion of the uterus, complicated with adhesions. The deformity of the uterus has been rectified by treatment, but the pain during the menstrual period is still as agonizing as ever. The most acute and intolerable anguish is felt in the left inguinal region, and is accompanied by a wind colic that causes the sufferer to writhe in agony. Nausea and vomiting add to her distress, and she seems at times ready to go out of her mind with suffering.

While still hoping to effect a permanent cure of this condition by appropriate treatment, temporary relief by the administration of morphia is all that I have hitherto been able to afford her; at the same time, that drug produces such disagreeable effects, that the remedy is only not quite so bad as the disease. It excites the nervous system, banishing sleep; it adds to the nausea, increases the prostration, destroys the appetite, and fails to keep off the wind colic. But on the last occasion, instead of morphia, I used cocaine, injecting subcutaneously over the left ovary, at first three, increased afterwards to five minims of a four per cent. solution. Almost immediately after each injection the pain in the inguinal region ceased to be felt, the nausea and wind colic were relieved, and, instead of nervous excitement and wakefulness, a soothing effect inclining to sleep was experienced. Five minims of a four per cent. solution were sufficient to afford complete relief for five or six hours, and comparative immunity for a much longer period.

While, however, the drug acted thus admirably, both locally and generally, it had no effect, apparently, on the bearing-down pains, and pain in the back, but only upon the local pain in the neighborhood of the spot where it was injected. It was also noticed that, while it relieved the nausea and vomiting of a reflex origin, it sometimes caused slight nausea itself, but this was only temporary. No other unpleasant effect was experienced, if we except a slightly bitter taste imparted to the tongue.

If cocaine can thus be made to supersede morphia in such cases, it will certainly prove an inestimable boon to many an unfortunate sufferer. And if it is able to relieve that excruciating intestinal pain usually called wind colic, which in so many cases is sure to follow the slightest surgical interference with the uterus, this of itself will be no mean trophy added to its many wonderful triumphs over human suffering.

German Views on Cocaine.

Considerable attention is given in the German medical press to the successes of cocaine as a local anæsthetic. Attention is drawn in the *Berliner Klinische Wochenschrift* to a claim to priority in the discovery of its value. Professor Rossbach, of Jena, writes that Dr. von Anrep, of St. Petersburgh, was the first who observed its local anæsthetic effect, and that Dr. von Anrep published an account of his observations, which he made in 1879 in Professor Rossbach's pharmacological laboratory at Würzburg, in Pfluger's *Archiv*, 1880, vol. xxi., page 38 *et seq.* He here points out its effect on the nerves of the skin and tongue, and on Page 70 recommends its trial as a "local anæsthetic" on human beings. In Professor Zuelzer's polyclinic at Berlin, cocaine has been used, with very susceptible people, on the urethra of men and women, from two to three cubic centimetres of a 2 per cent. solution of cocaine being syringed into the urethra, and retained there from three to four minutes. A diminution of susceptibility was always obtained, and sometimes perfect anæsthesia of the urethra, so that the catheter could easily be used. Professor Kahler, of Prague, reports a case of an unmarried woman, aged 38, who had suffered for years from hysteria, and for three weeks had been unable to take any form of nourishment through the mouth, owing to inappeasable vomiting. He painted the pharynx and base of the tongue with a 10 per cent. solution of cocaine, after which she was immediately able to take liquid, and soon afterwards solid food. Some valuable results are also published from Professor Jurasz's clinic for diseases of the larynx, throat, and nose, at Heidelberg; several experiments were made at Professor Jurasz's instigation by one of his pupils, on six medical men connected with the clinic, all of which, including a difficult operation, performed successfully and without pain to the patient by Professor Jurasz, justify the prophecy that this new material will be extensively and successfully used in the future.

A Painless Escharotic.

Drs. N. A. Randolph and Samuel G. Dixon thus write in the *Medical News*, January 24, 1885:

In the rapidly-growing literature of cocaine, it is not impossible that the application which we here briefly describe, has already been employed; but, if so, it has escaped our scrutiny of the later developments regarding this drug.

When a saturated solution of cocaine hydrochlorate in strong nitric acid is applied to the uninjured skin, the ultimate result is precisely that which would occur upon the similar application of pure nitric acid, but the time required for the formation of a deep eschar is considerably longer in the former than in the latter case.

We have experimented with the mixture just mentioned upon several individuals, ourselves included, and can safely say that the sensations

attending its application cannot be accurately described as painful. There is, however, a slight pricking sensation soon after the mixture is first dropped upon the skin.

Upon one person a control-experiment was instituted in the following manner: Upon his right arm were placed four drops of strong nitric acid, while upon the same point on his left arm was similarly disposed the same quantity of the mixture of nitric acid and cocaine hydrochlorate. The pure acid caused great pain, and was speedily removed; the mixture, which was applied later, caused a sensation described as "tickling, with slight pricking," which soon passed away.

In two cases the burned points were covered with absorbent cotton wet with a two per cent. solution of cocaine salicylate—a salt which we have not yet seen described, but which, in addition to the peculiar properties of its contained alkaloid, appears to be somewhat antiseptic. There has been no discomfort after the formation of the eschar. Prof. Harrison Allen, to whom we presented a portion of our solution of the salt last mentioned, kindly reports that he has applied it several times in his practice as a substitute for other salts of cocaine, with good results.

Rhigolene as an Anæsthetic.

In the *Canadian Practitioner*, Dr. G. S. Ryerson asks for more attention to this long-known local anæsthetic. He says:

"It is not a definite compound, but is the most volatile liquid known. When used in the form of a spray it is capable of freezing the tissues in about one minute, and producing a greater degree of cold than all other substances, except cymogene, whose boiling point is 32° F. It freezes more rapidly and deeply than ether; but as this effect is somewhat evanescent, the spraying must be frequently repeated during an operation, and may be kept up as long as required. Under a rhigolene spray both superficial and deep tissues can be freely divided, when properly exposed, without hemorrhage or pain; but owing to the rapid disappearance of the congelation, operations must be promptly carried out.

"I think that this drug may prove of considerable use in general surgery, inasmuch as the muriate of cocaine has not proved very useful when applied to the unbroken skin, and when injected hypodermically has caused unpleasant constitutional symptoms. In a previous number of the *Journal* I advised caution in its (cocaine) internal use."

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Several interesting cases of malformation of the female sexual organs resulting from arrest of development are described in a reprint by Dr. B. B. Browne, of Baltimore.

——A tabular arrangement, showing the character of the urine in disease, compiled by Dr. Louis Lewis, has been printed by the *Medical World*, of this city. It is a convenient and accurate presentation of the subject.

——Messrs. Parke, Davis, & Co., of Detroit, have published a suggestive pamphlet, entitled "Open Pharmacy and Scientific Substitutes for Proprietary Preparations, the Remedy for the Great Patent Medicine Evil." Their facts as well as their arguments and suggestions should receive the attention of the profession, as the question they broach is one of the most vital both to physicians and the public.

——The 55th Annual Report of the Philadelphia Lying-in Charity and Nurse School reminds us that it was this excellent institution which originated and organized the first nurse school ever in existence, and that too in days when to assume to teach nurses was almost a cause of obloquy and reproach.

——The 32d Annual Report of the Children's Aid Society, Philadelphia, shows that organization to be engaged actively in its beneficent labors.

——In an address on "The Revival of Ovariotomy," Sir Spencer Wells gives an admirable sketch of the history of the operation, and the gradual extension of its domain (London, J. & A. Churchill).

——Dr. A. W. Calhoun, of Atlanta, in a reprint on school hygiene, protests against the unwise cramming of children now so prevalent. He justly observes:

"Fewer hours of study and more rational methods of teaching, less cramming of mere memory and more healthy development of the intellect, will make brighter, healthier, and more intelligent students, who will develop into stronger, happier, more energetic men and women."

——An intelligent and honest discussion of the merits of the climate of New Mexico as a health resort is offered in an article by Dr. W. Thornton Parker, of Atlantic City, N. J. We commend it to all who think of going there.

——"Sugar of lead" forms the basis of so many lotions in eye surgery that the absolute condemnation of it by Dr. David de Beck, of Cincinnati, in a recent reprint, is worth attentive consideration.

——The Board of Education of Cleveland, Ohio, has printed, for general distribution, a series of "Brief Instructions as to the First Symptoms of Transmissible Diseases," by Dr. L. B. Tuckerman. The pamphlet is well and clearly written, and cannot fail to be of good service as a guide to teachers and superintendents of schools.

BOOK NOTICES.

Transactions of the Medical Association of Georgia. 35th annual session. Atlanta, 1884. 1 vol., 8vo., cloth, pp. 477.

In this handsome volume we have presented the proceedings of the meeting, the address of the President, Dr. A. W. Calhoun, the roll of members, necrological notices, and a large number of original papers and special reports.

One of the most noteworthy of the papers is by Dr. Battey, who details thirty consecutive cases of ovariotomy under antiseptic precautions, *all successful*. Dr. Gaston's explanation of the pathology and therapeutics of diseases of the nerve-centres is another valuable contribution. Dr. Eugene Foster discusses in a masterly manner the sociological bearings of syphilis. Dr. K. P. Moore enters a plea for the more general use of anæsthesia in natural labor, which we hope will be listened to favorably. In therapeutics, Dr. Lallerstedt writes of the uses of gelsemium, Dr. Hobbs of jequirity, Dr. Nunn of diet in consumption, Dr. Parks describes a new mammary bandage, and Dr. O'Daniel advocates the plaster-of-Paris dressing in fractures. Dr. McHatton maintains that leprosy is not contagious, and is only propagated by heredity. And there are other excellent papers which we have not space to specify.

Diseases of the Urinary and Male Sexual Organs. By William T. Belfield, M. D.

The Therapeutics of the Respiratory Passages. By Prosser James, M. D.

A Manual of the Medical Botany of North America. By Laurence Johnson, A M., M. D.

The above-mentioned three works belong to the issues of Wood's "Library of Standard Medical Authors" for 1884, and are published by the well-known firm of William Wood & Co., New York city.

We do not find in Dr. Belfield's work any new contributions to existing knowledge of the subject of which he treats. It appears to be little more than another presentation of familiar facts.

Dr. James has collected a great many observations and suggestions on his topic, and among them will be found a number which are worth remembering—and a number which are not worth it. The best part of his volume is that which discusses the hygienic measures, such as food, water, exercise, and rest, to which we look in the chronic forms of pulmonary trouble.

The Manual of Medical Botany of Dr. Johnson will satisfy in its botanical aspect, but we suspect will disappoint in its medical side. The "medical properties and uses" of the plants are passed over rather hurriedly, and not unfrequently either questionable authority given for the statements, or vague suggestions offered, which are not sufficiently precise to serve as guides. The volume has a number of wood-cuts, and some neat chromolithographs.

Official Register of Physicians and Midwives in Illinois. 1 vol., 8vo. cloth, pp. 324. Springfield, 1884.

This carefully prepared volume is a model for similar publications, and we heartily wish every state and territory in the Union would follow the example of Illinois in publishing such a record.

The Diagnosis and Treatment of Chronic Nasal Catarrh. By George M. Lefferts, A. M., M. D. 12mo., pp. 49. St. Louis, Lambert & Co.

The contents of this work are made up of three clinical lectures delivered at the College of Physicians and Surgeons, New York city. They are freely illustrated, showing the character of the lesions and the instruments used. For those who wish to post themselves on the character and management of this common complaint, the little volume will be found a desirable one.

Conspectus of the Medical Colleges of America. Revised to December, 1884. Compiled by the Illinois State Board of Health. 8vo., pp. 96. Springfield, 1884.

The object of this publication is to set forth the requirements which the various medical colleges demand of their graduates, and thus to offer a means of estimating their relative standing. The facts and statistics it presents give a better idea of what medical education is in the United States than all the addresses on the subject that have ever been issued. It is a volume which we commend to the consideration of all interested in the "elevation of the standard of the profession."

Insanity and Allied Neuroses; Practical and Clinical. By George H. Savage, M. D., etc. 12mo., cloth, pp. 544. Philadelphia, H. C. Lea's Son & Co.

This convenient, well-written, and well-printed volume is one of the series of manuals which we have already had occasion to commend. That it is written entirely from the English standpoint is somewhat against its value for American readers in what concerns the legal relations of the insane; but, of course, the strictly medical portions are as appropriate here as there. The now acknowledged fact that insanity is steadily on the increase in most civilized countries attached a growing importance to its study.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Quarterly Compendium of Med. Science, -	2.50
Reporter and Compendium. - - - -	6.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - - -	6.25
Reporter, Comp. and Pocket Record, - -	7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM,* which we publish.

It is, in fact, a supplement to the *REPORTER,* being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE CARE OF THE INSANE.

For some years past, in this country, and notably in our own State, that large and growing class of our population, who for some reason or other have lost the ability to care for themselves, has been attracting a large measure of the thoughts of our philanthropists and legislators. The insane of our day are very much better provided for than were those bereft of reason half a century ago; and we find many more human beings confined in asylums. When we stop to reflect upon the subject, the thought comes to us, whether this very improvement in the accommodations offered to insane patients, has not had something to do with the apparent increase of insanity in our time.

We recently visited the Hospital for the Insane, at Norristown, in this State, and upon asking Dr. Harris, the courteous resident physician, to what cause he attributed the cases of insanity under his care, he answered, "The causes are various, but chiefly *alcohol* and *syphilis.*"

The question then suggested itself whether the consumption of alcohol and the prevalence of syphilis is any greater to-day than it was a generation ago. We do know, and have always recognized, that the abuse of alcoholic liquors will in many instances produce an unsettled state of the mind, and oftentimes will render its victim absolutely insane; and the same can, of course, be said, with truth, about syphilis. When we walked through the wards of this magnificent institution, we thought that we saw many men not one whit more insane than are many of those whom one meets daily upon the street. Of course, it is not always an easy matter to pass a verdict upon a man's sanity or insanity, but it seemed that there were some men who were merely harmless cranks, and whose confinement in an asylum seemed hardly necessary to the welfare of the community. The appointments of this institution are very fine, and we do not hesitate to say that the majority of the inmates are now surrounded with many more comforts than they ever enjoyed in their own homes. We do not mean to decry the care of the insane, and we would not deprecate a single effort to restore these poor unfortu-

nates to mental health and to usefulness in the community; but, to repeat, we ask the question, whether the erection of these magnificent institutions, containing the finest of appointments, do not have a tendency, more or less marked, to encourage a weak intellect to give way to its weakness.

They are exceedingly expensive both to erect and to conduct, and thus they constitute a great drain upon the tax-payers of the State. Are we, as a people, any better off, any happier?—is there any less crime, pauperism, or misery, since, than there was before the erection of these expensive institutions? Without being very accurately informed on the statistics of these subjects, which, after all, do not prove very much, we are inclined to think, from daily observation, that the question can be answered in the negative.

In conclusion, we wish to be understood as having the greatest sympathy for the truly insane, but we wish also to suggest that the luxuries of our great modern asylums may not be altogether unmixed blessings.

SHALL WE SLEEP WITH OPEN WINDOWS?

The other day a gentleman in our office remarked:

"I have had no bad colds since I learned to sleep with my windows open."

Now it had been our personal experience that the only "hard colds" we had ever suffered from were contracted precisely by sleeping in rooms to which the night air had free access.

This is a vital point in personal and domestic hygiene, about which the opinions of advisers differ diametrically.

It is well known that the bodily temperature sinks slightly during sleep; the physiological functions act with diminished activity; and hence the resistance of the economy to morbific influences is proportionately lessened.

But it is also well known that at night these influences are more potent and noxious. The air is charged with greater humidity; miasmatic and malarial poisons rise to higher levels, and extend with greater rapidity; the chill of the damp night air is penetrating and dangerous; the emanations from organic decay are more perceptible.

Against these the sleeper is less protected than in the daytime. He has divested himself of his woolen external clothing to put on cotton or linen, and lies between sheets of the same material, between which, at the tops and sides of the bed, the air gains ready access to his unprotected surface. If he is restless, he renders such access yet more easy.

A greater risk awaits him. A sudden fall in temperature at night is no unusual occurrence. In summer a thunder gust, in winter a shift of the wind to the north, often reduces the temperature ten to twenty degrees. The sleeper is unaware of this. He remains exposed to it with no further protection than he found agreeable at the higher temperature until he awakes chilled and stiff, perhaps with the seeds of a serious illness already sown.

These are such positive and unavoidable risks that we should counsel a delicate person to be exceedingly cautious how he ventured on the plan of open windows at night, however much has been said in its favor by popular hygienists.

CLINICAL THERMOMETRY.

With the advent of medical thermometry a new field was opened to scientific as well as clinical activity. It became necessary to have instruments registering with greater precision than those ordinarily found in the shops. Hence, the establishment of thermometric bureaus, as that at Yale College in this country.

How enormously the medical business preponderates in such establishments is evident from the Yale report before us for the year ending June, 1884. Out of a total of 6,390 examined, not less than 6,326 were physician's clinical thermometers!

An examination of the various causes of errors in thermometers shows that such fluctuations arise from widely different causes. The negligence of the manufacturers may produce imperfect instruments. Others are correct in portions of the tube, but quite wide of the mark in other portions.

But aside from results of carelessness, there are other causes of error inseparable to the nature of the instrument. On account of the unstable nature of glass the size of the thermometer's bulb constantly varies. The rapidity and amount of these changes depend upon the manipulation of the maker, the time elapsed since manufacture and the use to which it has been subjected. For a thermometer over a year and a half old, this change is seldom more than fifteen hundredths of a degree Centigrade in a year. For a thermometer over two years old seldom more than a tenth. During the first year it may amount to a degree or more. The change may take place suddenly or grow slowly.

In self-registering instruments the index may introduce errors by slipping in the tube, or by moving by jerks.

As the utmost possible accuracy is desirable in a thermometer intended to test temperature in disease, such institutions as that at Yale cannot fail to be a marked benefit to the diagnostician.

Notes and Comments.

The Application of Cocaine to the Urethra.

The *London Medical Times* tells us that several communications upon this subject have recently been published. Dr. Blumenfeld states in the *Deutsche Medicinische Wochenschrift*, Dec. 11, that he has found the introduction of a small quantity of a two per cent. solution into the urethra by means of a small syringe (keeping the orifice closed for three or four minutes), highly useful in irritable urethra, the irritability being diminished in all cases, and the urethra often becoming anæsthetized completely as far as the posterior part of the prostate. The anæsthesia continues nearly half an hour, and may be prolonged greatly by the frequent employment of a somewhat larger dose. Where the mucous membrane is visible it is found to be remarkably pale in color. Dr. Blumenfeld, although he has had no opportunity as yet of trying the experiment, believes that in some cases of retention of urine, relief will be obtainable from the cocaine alone, without resorting to the catheter. He also suggests that a three or four per cent. ointment may be advantageously carried to the posterior parts of the urethra by means of a caustic-holder. Dr. Fessenden Otis, writing in the *New York Medical Journal*, December 6, after referring to the gratifying results which Professor Pease, of Syracuse, had obtained from the use of a four per cent. solution in an operation for stricture, and also for the relief of a sensitive urethra, gives an account of his own trials made with a two per cent. solution. Dilatation of a very sensitive urethra was effected without the least pain, prior to an operation for lithotomy. In another case, in which sounding for calculus had been only imperfectly performed, it was soon achieved by the aid of cocaine, a stone detected, a narrowed orifice and a stricture divided, and all without any pain. A case in which enlarged prostate was associated with such a state of hyperæsthesia of the urethra that all attempts at passing a catheter and washing out the bladder had been abandoned for weeks, a catheter was passed and the water drawn without any pain whatever. Other similar cases are referred to, and in relation to them Dr. Otis remarks that the best means for giving relief to irritable urethræ, especially when combined with prostatic trouble, "is to attach a tight-fitting half-ounce penis-syringe to the open end of a rubber catheter of 18 or 20 mm. in circumference. After pouring the solution into a small graduate, draw a sufficient quantity up into the catheter. Introduce it for half-an-inch, or until the patient complains of pain, and then press down the piston, gradually driving a few drops in advance of the catheter, rubbing it along with the finger, waiting from three to five minutes, then passing it down about two inches further, and repeating the process of coaxing the fluid back until finally the end of the catheter enters the bladder, consuming altogether about fifteen minutes." The value of cocaine will be found equally great in examinations and operations in irritable anus and rectum. "A four per cent. solution of cocaine in almond oil makes an excellent lubricant for urethral instruments, and I think may prove even better than the watery solution as an application to the urethra. Its use in this way in a few cases has been very satisfactory." In Baltimore, surgeons use cocaine extensively in venereal diseases, Dr. Michael finding it very useful in opening buboes and cauterizing sores. We may refer also to a case narrated by Dr. Croston in the *Boston Medical Journal*, December 11, in which a four per cent. solution of cocaine was employed hypodermically in the removal of an epithelioma of the cheek, four or five injections of four minims each being employed. Without absolutely preventing pain, the operation was rendered easily bearable.

Tonsillitis in Relation to Febrile Attacks in Childhood.

We have all been called upon at different times to see children suffering from feverish attacks where the greatest acumen and the most careful examination fails to reveal any adequate cause. In many such cases, a writer in the *London Med. Times* (January 10, 1885,) tells us that we will find a tonsillitis. Sometimes, but rarely, there will be complaint of pain in the throat.

It is, perhaps, in instances of recurring pharyngitis in children of four years old and upwards that we shall find the remembrance of what has been said most useful. Very often do cases occur where a child is said to have feverish attacks every now and then by mother or doctor, for which it is put to bed and physicked a little, and recovery takes place in a few days. In the intervals these children are generally regarded as being quite well. But they are often of a muddy complexion and capricious in their appetite, and are seen to have chronically enlarged tonsils. The acute attacks supervening on this chronic condition from time to time are liable to be very slight as far as local trouble goes, and consequently are just the cases which we would especially wish to emphasize as being often overlooked. A routine examination, therefore, of the throat should be made in all cases of feverish illness in children, whether or no, complaint be made of pain, and the doctor will be often satisfactorily rewarded by at least the possession of a definite idea as to the nature and cause of the malady he has to pronounce upon and treat.

On the causal connections of these pharyngeal affections in children but a word can be said. They do not seem to be simply catarrhal, or due to exposure, with any great frequency. But they often occur in strumous children, especially in connection with chronically-enlarged tonsils, and very frequently, indeed, in those of a rheumatic or gouty inheritance.

The treatment of the acute attacks does not require any special notice here, but in many cases of chronically enlarged tonsils, excision is of unquestionable value, as minimizing or, perhaps, almost abolishing the acute evil.

How to Give Iodide of Potassium in Syphilis of the Nervous System.

This is a very important subject, because on account of faulty methods of administration many men have lost their faith in the efficacy of this valuable drug.

Dr. William A. Hammond, after stating that the drug must be given in large doses, thus concludes in the *New England Medical Monthly*, January, 1885:

"But there is a point connected with its administration that is, I think, equally important, and that is, that the doses should be increased from day to day. Iodide of potassium is one of those remedies that are rapidly eliminated from the system, and which, therefore, are inert, or almost so, if the dose be maintained at a fixed quantity. It should, therefore, in order to secure its full effect, be given in what the late Dr. E. H. Clark, of Boston, called the "continuing dose," *i. e.*, in increasing doses. Without large doses, I am satisfied that many cases of syphilis of the nervous system that are curable go unrelieved, and unless the doses are gradually increased the stomach is not apt to bear them well. In the way that I have mentioned, and taking care to give it after meals and in a large quantity of water, a dose of two hundred grains will be as well borne by the stomach and the system generally, as one of five grains. Large doses should not be gulped down at a single draught. A dose of from fifty to two hundred grains should be taken in from half a pint to a pint or more of water, and the patient should take it by sips during fifteen minutes or half an hour. In this way I am satisfied its action is increased and the liability to derange the stomach reduced to a minimum."

Cannabis Indica in Sick Headache.

Any drug that will relieve this obstinate and distressing complaint is well worthy of mention. Dr. Francis F. Brown tells us in the *Boston M. and S. Jour.*, October 23, 1884, that he has had good results from the use of cannabis indica. His experience has been quite limited, but he has had a few patients whose improvement from its use, after the failure of tonic treatment alone, has been very marked. One case, a lady of thirty-three—whose mother suffered all her life from migraine, and father from migraine and asthma—who had been having attacks increasing in severity and frequency for months, till she was having one nearly every week, each attack lasting two or three days, experienced immediate relief, and while she had threatenings did not have a decided attack for six months. This was three years ago; her improvement, though not immunity, has continued.

Though some begin to feel relief at once, the drug should not be considered to have had a fair trial till after months of continuous use. He has seen patients relieved after persevering four or

five months who saw little or no benefit in three. The notorious uncertainty of the quality of this drug is a decided drawback to a satisfactory trial of it. What proportion of cases will be benefited by it, and how permanent will be the relief, he is not prepared to say.

Gonorrhœa in the Female.

We have already referred to Dr. Currier's papers on this subject in the *New York Med. Jour.*, and now, in the issue of January 24, 1885, we find his conclusions as follows:

1. Gonorrhœa in the female deserves more thorough investigation than it has yet received, especially in the light of recently-established facts.

2. The diagnosis of the disease, with improved methods of investigation, chief among which are Sims's speculum and the microscope, is not so difficult as it has hitherto been considered, even in the absence of direct information of actual exposure to gonorrhœal infection.

3. There is a difference between the characteristic discharge of true gonorrhœa, as to both its nature and its effects, and other mucoid discharges from the female genital tract. As a corollary to the foregoing statement, while investigators differ as to the significance of the micrococcus of gonorrhœa, its constant presence in the discharges is not denied.

4. Gonorrhœa in the female is identical with gonorrhœa in the male. The fact of individual peculiarities and susceptibilities is not questioned.

5. A series of careful investigations upon well-defined cases, in a hospital or other place in which the changes and developments can be accurately noted, is desirable. No line of treatment can be recommended as unfailing and entirely satisfactory until the results of such investigations are known.

Rhigolene.

Truly there is very little "new under the sun." The excitement over cocaine as a local anæsthetic has caused some gentlemen to revive rhigolene, which, some years ago, was highly vaunted as a local anæsthetic, used in spray form. It was then claimed that it acted as a refrigerant, and would so effectually freeze the part upon which the spray was directed as to obtund or destroy its sensibility. It did not seem to give satisfaction, however, for its use was soon discarded. It does have some effect in destroying sensibility, as we know from personal experience; but its effects are very evanescent, and it is necessary that the spray shall be continuously directed on the part throughout the whole of the operation, which must necessarily interfere with the surgeon's manipulations to a greater or lesser extent. It might be used in conjunction with cocaine. When not in use it should be kept on ice or in a cool room, tightly corked. In a warm place it would probably burst the bottle or blow out the cork. It has been accused of possessing explosive properties, but probably it is safe if not brought in contact with an open flame. It should not be used for cases which require artificial light.

Tardy Constitutional Syphilis.

To the New York Clinical Society (November 28, 1884), Dr. L. B. Bangs related the case of a man who had a sore on the pubic region in 1872, which healed in a month, and was followed by no further manifestations until 1881, when a lump as large as a hazel-nut appeared just over the episternal notch. During the following winter the patient was subjected to hardships and lost strength; at the same time the lump increased in size and became red and painful. A traveling physician opened it and cauterized it, but only a little discharge took place. In a short time a like growth appeared upon the clavicle, became red and painful, discharged and speedily closed. The patient was now treated for syphilis, and took a Turkish bath every day for four months, but his debility increased. In 1883 he was still growing feebler, and had ulceration of the throat, when he presented himself to another physician, who diagnosticated syphilis, gave mercury in tonic doses, and effected a cure in four weeks.

The peculiar features in the case were the absence of all symptoms during the nine years that followed the initial lesion, and the fact that the scars left by the growths were not circular but linear.

Multiple Fracture of the Bones of the Upper Extremity.

As a matter possessing much interest, we note the following case which Dr. Puzey exhibited before the Liverpool Medical Institution at its meeting December 4, 1884:

The patient was a man admitted into the Northern Hospital in December of last year. Whilst oiling some machinery at rest, it was suddenly put in motion: the man's arm was caught in a fly-wheel, and he was thrown down. On admission into the hospital, the arm was so much swollen that the injuries could not be accurately ascertained,

and a patient attempt was made to preserve the limb. In November last, however, disorganization showed itself in the wrist-joint and the second phalangeal joint of the middle finger and the arm was amputated. Amongst the injuries brought to light were the following: Oblique fracture of upper part of humerus, below this a united oblique and comminuted fracture, and below this again a ununited fracture. In the upper part of the fore-arm was a comminuted fracture of radius and ulna: in the lower part a fracture of the radius that had united to the ulna.

The Treatment of Acute Laryngitis.

Dr. John M. Keating tells us in the *Archives of Pediatrics*, January 15, 1885, that he has frequently found the following treatment very efficacious:

In conjunction with a hot foot-bath, the temperature of the water as hot as the hand can bear with comfort, and the feet afterwards wrapt in flannel or Canton-flannel night-drawers with the feet of extra length and sewed up at the extremities, he prescribes the following in a half tumblerful of water:

℞.		
	Tinct. aconit rad.,	gtt. iij.
	Spts. ætheris nit. dulc.,	ʒj.
	Syr. scillæ co.,	ʒj.

This is given in frequently-repeated dessertspoonful doses throughout the night. A soft handkerchief wrung with ice-cold water and surrounded by a silk one or a piece of flannel is applied.

If the cough continues, and becomes bronchial, it is well to produce a certain amount of counter-irritation of the chest. Ordinary camphorated oil is about the best. In addition to the ipecac, we should recommend small doses of castor oil, the object being to relieve the congestion of the bronchial mucous membrane by acting on the intestinal mucous membrane.

Excision of a Tumor from the Brain.

Some time since we reported the performance of this operation in London, and we are now called upon to note its fatal sequence. The operation was performed November 25, and the patient did well until December 15. On the morning of the 16th he was suddenly seized with a rigor, followed by fever, sickness, and pain in the head. A hernia cerebra of large dimensions supervened. The pyrexia increased and continued, the patient emaciated, gradually sank, and died on December 23, the intelligence remaining intact to the last.

On post-mortem exrmination meningitis was found at the lower border of the wound, spreading downwards towards the base of the brain on the same side, the whole of which was inflamed and covered with plastic lymph. With the exception of the loss of cerebral tissue, caused by the operation, the brain was otherwise practically normal.

Chorea Successfully Treated with Chloroform Inhalations.

Before the Liverpool Medical Institution (December 4, 1884), Dr. Bostick related the history of a case of chorea in a young girl, wherein conium, chloral, bromide of potassium, etc., all proved useless. Chloroform was therefore given to produce sleep, and a very little had the desired effect; it was, therefore, repeated when necessary. This was continued for eight days; but, as soon as she was allowed to come round thoroughly, she was as violent as ever; the chloroform was therefore given continuously for forty-eight hours, at the end of which time, the movements being much more easily restrained, the limbs were wrapped in cotton-wool, and firmly bandaged to the bed. This seemed to be of great service to her; and, from this time, she gradually improved, and ultimately made a rapid and complete recovery.

Albuminuria After Chloroform.

From an English exchange we learn that M. Ferrier, one of the surgeons attached to the Bichat Hospital, and M. Patein, its resident chemist, have made a series of researches to discover the condition of urine after administering chloroform, followed by surgical operations. In six cases out of nine, albumen was present in the urine. The presence of albumen in urine has apparently a closer connection with the anæsthetic condition than with its duration. In some cases chloroform was administered during 20, 45, and 55 minutes without the slightest trace of albumen being found in the urine. The result of these researches indicates that there are certain pathogenic conditions connected with the appearance of albumen in urine which have not yet been elucidated. M. Bouchard's interesting experiments taught that albuminuria may be provoked by lesions of the peripheral nervous system, also from inhaling chloroform, even in small doses.

Osmic Acid in Sciatica.

All contributions to the therapeutics of this most painful and obstinate disease are worthy of

record, since our present methods of treatment are not very satisfactory. Dr. Jas. Merces reports in the *Lancet*, January 10, 1885, his experience with osmic acid in eighteen cases. He used a one per cent. solution, injected, in doses of from three to five minims, deeply over the sciatic nerve, at a point midway between the tuber ischii and trochantor major. It produced no constitutional effects, but locally at the seat of the puncture the patient invariably complained of a numb feeling, which, however, was transient. In some cases the effect was marvellous, the patient being able after a short time to stand on the affected side, a feat which he had been unable to do for years.

Successive Craniotomies in the Same Subject.

It is usually believed that craniotomy is an operation that possesses dangers for the mother, and on this account some men hesitate to perform it. While we imagine that when unskilfully performed it may prove very serious in its consequences, yet the case which Dr. Fancourt Barnes reports in the *British Med. Jour.*, January 10, 1885, would seem to show that the operation need not be so much dreaded as far as the mother is concerned. In the case in question, the woman was successfully delivered by craniotomy on six occasions.

Correspondence.

Embolic Hemiplegia.

Eds. Med. and Surg. Reporter:—

The patient whose case I am about to report died very suddenly on January 5, 1885, while in the act of correcting a pupil in the district school he was at the time teaching. He was 24 years of age. On May 11, 1882, being then convalescing from an attack of subacute endocarditis, while walking in a field near his home he was suddenly seized with a severe pain in the head and fell to the ground. He was carried to the house and I was summoned. When I arrived he was perfectly unconscious, and paralysis of motion and sensation of the left side of the body was complete. Hemiplegia from cerebral embolism was at once diagnosticated, the knowledge of the history of his case previously aiding somewhat in the diagnosis. On the second or third day after this the patient manifested great pain in the right arm. Upon examination, discovered the right subclavian artery was occluded by an embolus, so that no blood passed into the brachial artery. In the course of six or eight hours this obstruction moved down to the bifurcation of the brachial artery. Here it remained, and the collateral circulation was established, but no pulsation could be felt in the radial artery for ten days. The skin of the little finger sloughed, but was finally reproduced. The treatment thus far had been medicinally, by amm. carb. and small doses of digitalis and opium. Gradual improvement occurred, and during the following winter, 1882–1883, he began to stand and walk with the aid of a person at his left side. The faradic current of electricity was used through the muscles of the left arm and leg. During the summer of 1883 he was able to walk with a crutch. In the winter of 1883–1884, continued his studies at the normal school, his mental faculties being in a perfect condition. Spring and summer of 1884 did a good deal of bracket work with a scroll saw, although the left hand was paralyzed so far as the extensor muscles were concerned, Fall of 1884 taught a district school of 23 scholars, and began the same school the present winter, when his career suddenly ended, as described in the beginning of this report.

Autopsy forty-four hours after death.—Upon removing the calvaria a large quantity of serous fluid escaped on the right side. Separating the convolutions near the anterior border of the right middle cerebral lobe, a cavity large enough to contain a good-sized hen's egg was discovered. This cavity was the course of the fluid above spoken of, and which escaped through a small rent in the sac that confined it. Otherwise the brain and its membranes were healthy. Slight fatty change was found at the base of the mitral valve. At the origin of the large pulmonary veins at the root of the lungs, and contained within their calibre, was found as much as a dessertspoonful of bony or calcareous matter. The apices of both lungs showed deposits of caseous matter, as evidence of former disease there. Other organs not examined.

The cause of instant death was thought to be nervous excitement, causing an increased circulation through the brain, which ruptnred the sac that enclosed the fluid in the cavity. This produced a shock which caused the weakened heart to stop its work. It would also appear that the source of the embolus in the spring of 1882 was the pulmonary veins or endocardium, and that the first one went into the right middle cerebral artery, and the one that followed a few days later into the subclavian artery of the right side.

Bethel, Vt., January 22, 1885.

Curious Case of Foreign Body in the Bladder.

Eds. Med. and Surg. Reporter:—

During a recent Cuban revolt, one of the soldiers, an Americo-Cuban patriot, while on the field, was "brushed" by a solid shot which passed within a short distance of his abdomen. He thought no more about it, except that he was somewhat shocked, having been thrown to the ground by the force of the passing ball. In a few hours he thought he would empty his bladder, but found himself unable to do so. Surgeons were scarce, but finding a wounded officer upon the ground he stopped to help him, and together they reached a place of security near a swamp, where, after making the officer comfortable, he acquainted him with the trouble he had with his bladder, which by this time was wellnigh unbearable. The officer having some knowl-

edge of surgery pulled a reed from the swamp, and after clearing out the pith managed to pass it, and gave the soldier relief. They were both so pleased with the result that the reed was tied in place and not removed until the following evening.

No trouble was experienced until about three months afterward, when the soldier, who had made his way to the United States, found the urine voided with more and more difficulty, until he applied to Dr. Jos. Dickson, Pittsburgh, Pa. The sound showed a foreign body about at the membranous portion of the urethra. The left lateral operation was made, and as the sound would go no further than the obstruction, Dr. Dickson cut for the point of the sound. In feeling for the stone, his finger pushed the obstruction into the bladder, and from this time the ordinary operation was done. When the stone was extracted, it was found to be the size of a large hickory-nut, with an elongated process on it. This process had occupied the lower portion of the urethra, and was a complete mould of it, even to the little projections into the vesiculæ-seminales. The large knob end was of course in the bladder. When it (the stone) was examined, a piece of the reed which had broken off three months before was found in the centre, and around which the concretion had formed. When the patient recovered from the anæsthetic, he gave the story as detailed above, which he had not previously told, as he did not connect that with his trouble. The reed was jointed, and had separated at one of the joints. The recovery was complete.

Allegheny, Pa.

Jaborandi for Inflammatory Affections of the Skin.

Eds. Med. and Surg. Reporter :—

In the *Therapeutic Gazette* for November, Dr. Thompson, of Tennessee, says that he has been treating erysipelas for several years with jaborandi. Recalling the fact that this drug has, or is supposed to have, special affinity for the skin, when given by the mouth, I determined to test its efficacy in all forms of inflammatory conditions of the skin, and soon opportunity offered in the following cases :

Case 1. A well-marked case of erysipelas of the face, starting from the nose. I saw the man late in afternoon. Gave pill hydg., gr. x., at bedtime ; followed in morning by saline, and gave—

℞. Fl. ext. jaborandi, ℥ j.
Tr. opii,
Glycerin., āā ℥ ss. M.

Sig.—Paint over the part with chicken feather every two hours.

Continued treatment for three days, when I considered the patient cured.

Case 2. A lady, with irritable spine, was in the habit, at certain times, of applying a counter-irritant of croton oil ; but this time she used too much, and by some means the effect was diffused over the whole surface of the body. When I was called, three days later, the whole surface of the body was extremely red, painful, and œdematous. All the usual domestic remedies had been tried without effect, at least without benefit. I ordered the mixture, as in case one, to be used. The pain was relieved almost instantly, the redness and swelling gradually subsided, and on the third day there was nothing left of the inflammation, but an abundant exfoliation of the cuticle was going on, which finally left the skin in excellent condition.

It may be proper to add, that in this case I ordered the woolen underwear to be exchanged for cotton, and gave a slight purge with Epsom salts.

Case 3. My wife severely scalded her hand with boiling liquid. It was remarkably painful, and the burned surface covered most of the hand. When I saw her about half an hour after, I saturated a compress with equal parts of fl. ext. jaborandi and laudanum, and applied to the burned surface. This totally prevented the inflammatory action, which I am sure would have followed from the severity and extent of the scalded surface.

From my experience with this limited number of cases I am sure that we have in this drug a valuable addition to our therapeutics of acute inflammatory affections of the skin. In proper combination it acts quickly and efficiently.

Dunbar, Neb., January 21, 1885.

Injections of Carbolic Acid in Abortion.

Eds. Med. and Surg. Reporter :—

An excellent article in the Med. and Surg. Reporter for January 17, by Dr. Coover, particularly attracted my notice, it being on "miscarriages," which for many years I have treated in precisely the same manner, except I would add to the doctor's excellent treatment one indication, which, being answered and followed out, has, I believe, in several of my cases, saved human life. I refer to those cases where the ovum or fœtus and placenta are not expelled at once, but come away piecemeal and in a decomposed condition ; at such times daily warm vaginal injections of carbolic acid and water have answered the indication and completely filled the bill.

News and Miscellany.

The Medical Profession in the Argentine Republic.

While we were aware that good physicians are in demand in South American countries, we were hardly prepared for the following account, which we find published in the *Brit. Med. Jour.*, January 10, 1885 :

The prospects of the medical profession in the Argentine Republic, as related in the *South American Journal*, are of an unusually satisfactory character ; and in these days, when the cry of overcrowding is heard from every profession (and the medical profession is no exception), the following statements will be read with refreshing interest, and give to the despairing hope.

"All the medical men here are said to be making fortunes, and there is still room for 'healthy competition.'

"The ordinary charge for a consultation at a medical man's house is said to be two dollars; for a visit, four dollars; for attendance at confinement when all goes well, about $100; but when any special care or operation is required, these fees mount up to hundreds of dollars. Accounts for medical attendance are sent in and paid without remark, which would make the hair of a paterfamilias in the 'old country' stand on end. My friend mentions the following fees as having been lately obtained by doctors who, though of good standing, are not looked upon as 'stars:' for extraction of ovarian tumor, $7,000; amputation of arm, principal, $300; amputation of arm, two assistants, each, $2,000; delivery, with operation, $2,000; attendance during typhoid fever, $1,000; visit by a physician for dropsy, $250; consultation-fees, $100 and upwards.

"Much depends, of course, on the position of the patient, but there are sufficient wealthy people to make up for any small fees or gratuitous work which may have to be done among the poorer classes.

"Nor are we led to believe that there are any serious drawbacks to this pleasant outlook. The Argentine Republic, which, as is well known, comprises a vast area of fertile territory, extending from the tropics down to Cape Horn, with a firm and settled government, has a climate pronounced to be one of the most temperate in the world, and should be the healthiest; but, owing to defective sanitary arrangements, it is not so. Buenos Ayres, with a population of about 300,000, has a mortality of 33, which it may reasonably be expected will be considerably lessened in view of the extensive drainage and water-works now in course of construction.

"Expenses are, of course, much higher in South America than in Europe, and it would be unwise to compare charges in two places without taking this into consideration.

"In the city of Buenos Ayres, there are said to be now practicing about a dozen English-speaking doctors, all doing well. In other large cities of the interior and in the country, there are a good number to be found. But immigration is flowing into the country, and everything growing so fast, that there seems to be no fear of overcrowding.

"Owing to the facilities offered in the government schools and universities, a young man in the Argentine Republic obtains a complete education free from all expenses in fees. The medical schools are well attended, and the natives prove apt scholars. The standard (so far as my friend can judge, he not being of the medical profession) seems to be as high as in European universities, and there are many Argentine doctors who would take a high rank in their profession in any part of the world. Besides these native taught doctors, there are in practice in the Argentine Republic many medical men of every European nationality; and, at a first glance, one would think that the profession was rather over-crowded.

"However, when one sees that nearly all the doctors are making fortunes, and hears of the enormous fees which they can easily obtain, he perceives that there is still room for 'healthy competition.'

"The statements given above are confirmed by another correspondent, who states that a friend of his paid £100 for attendance at the confinement of his wife; and adds that the charges by dentists are on a like magnificent scale, as much as £5 or £6 being paid for stopping a tooth. There, however, appears to be one important condition: before a doctor is allowed to practice in the Argentine Republic, he must pass an examination, and be licensed by the Government Medical Board: and before he can do this he must, of course, be master of the Spanish language. The population of the country is so cosmopolitan, that the more modern languages he speaks, the better will be his chances of success."

An Estimate of Dr. Holmes.

From a critical paper by Edmund C. Stedman in the February *Century* we quote the following: "If the question is asked, Would the verse of Doctor Holmes be held in so much favor if he had not confirmed his reputation by prose replete with poetic humor and analogy? The fairest answer may be in the negative. Together, his writings surely owe their main success to an approximate exhibition of the author himself. Where the man is even more lively than his work, the public takes kindly to the one and the other. The jester is privileged even in the court of art and letters; yet if one could apply to Holmes—the jester, homilist, and man of feeling—his own process, we should have analysis indeed. Were the theme assigned to himself, we should have an inimitably honest setting forth of his merits and foibles, from this keen anatomist of mind and body, this smile-begetter, this purveyor to so many feasts. As a New Englander, he long ago was awarded the highest sectional praise—that of being among all his tribe the cutest. His cleverness and versatility bewilder outside judges. Is he a genius? By all means. And in what degree? His prose, for the most part, is peculiarly original. His serious poetry scarcely has been the serious work of his life; but in his specialty, verse suited to the frolic or pathos of occasions, he has given us much of the best-delivered in his own time, and has excelled all others in delivery. Both his strength and weakness lie in his genial temper and his brisk, speculative habit of mind. For, though almost the only modern poet who has infused enough spirit into table and rostrum verse to make it worth recording, his poetry has appealed to the present rather than the future; and, again, he has too curious and analytic a brain for purely artistic work. Of Holmes as a satirist, which it is not unusual to call him, I have said but little. His metrical satires are of the amiable sort that debars him from kinsmanship with the Juvenals of old, or the Popes and Churchills of more recent times. There is more real satire in one of Hosea Biglow's lyrics than in all our laughing philosopher's irony, rhymed and unrhymed. Yet he is a keen observer of the follies and fancies which satire makes its food. Give him personages, reminiscences, manners, to touch upon, and he is quite at home. He may not reproduce these imaginatively, in their stronger combinations; but the Autocrat makes no unseemly boast when he says: 'It was in teaching of Life that we came together. I thought I knew something about that, that I could speak

or write about it to some purpose.' Let us consider, then, that if Holmes had died young, we should have missed a choice example of the New England fibre which strengthens while it lasts; that he has lived to round a personality that will be traditional for at least the time granted to one or two less characteristic worthies of revolutionary days; that ''twas all he wished'—a few of his lyrics already belong to our select analogy, and one or two of his books must be counted as factors in what twentieth-century chroniclers will term (and here is a matter for reflection) the development of 'early' American literature."

General Grant's Accident at Shiloh.

From General Grant's illustrated account of the Battle of Shiloh, in the February *Century*, we quote the following: "In fact, on Friday, the 4th, I was very much injured by my horse falling with me and on me while I was trying to get to the front, where firing had been heard. The night was one of impenetrable darkness, with rain pouring down in torrents; nothing was visible to the eye except as revealed by the frequent flashes of lightning. Under these circumstances I had to trust to the horse, without guidance, to keep the road. I had not gone far, however, when I met General W. H. L. Wallace and General (then Colonel) McPherson coming from the direction of the front. They said all was quiet so far as the enemy was concerned. On the way back to the boat my horse's feet slipped from under him, and he fell with my leg under his body. The extreme softness of the ground, from the excessive rains of the few preceding days, no doubt saved me from a severe injury and protracted lameness. As it was, my ankle was very much injured; so much so, that my boot had to be cut off. During the battle, and for two or three days after, I was unable to walk except with crutches.

* * * * *

"During the night rain fell in torrents, and our troops were exposed to the storm without shelter. I made my headquarters under a tree a few hundred yards back from the river bank. My ankle was so much swollen from the fall of my horse the Friday night preceding, and the bruise was so painful, that I could get no rest. The drenching rain would have precluded the possibility of sleep, without this additional cause. Some time after midnight, growing restive under the storm and the continuous pain, I moved back to the log-house on the bank. This had been taken as a hospital, and all night wounded men were being brought in, their wounds dressed, a leg or an arm amputated, as the case might require, and everything being done to save life or alleviate suffering. The sight was more unendurable than encountering the rebel fire, and I returned to my tree in the rain."

The Origin of Opium.

The *Popular Science News* tells us that according to the Bengali legend, there once lived, on the banks of the holy river Ganga, a Rishi, or sage, in whose hut, made of palm leaves, there was a mouse, which became a favorite with the seer, and was endowed by him with the gift of speech. After a while, the mouse, having been frightened by a cat, at its earnest solicitations was changed by Rishi into a cat; then, alarmed by dogs, into a dog; then into an ape; then into a boar; then into an elephant; and finally, being still discontented with its lot, into a beautiful maiden, to whom the sage gave the name of "Postomani," or the "poppy-seed lady." One day, whilst tending her plants, the king approached the Rishi's cottage, and was invited to rest and refresh himself by Postomani, who offered him some delicious fruit. The king, however, struck by the girl's beauty, refused to eat until she had told him her parentage. Postomani, to deceive the king, told him she was a princess, whom the Rishi had found in the woods, and had brought up. The upshot was, that the king made love to the girl, and they were married by the holy sage. She was treated as the favorite queen, and was very happy; but one day, whilst standing by a well, she turned giddy, fell into the water, and died. The Rishi then appeared before the king, and begged him not to give way to consuming grief, assuring him that the late queen was not of royal blood. Said he: "She was born a mouse, and, according to her own wish, I changed her successively into a cat, a dog, a boar, an elephant, and a lovely girl. Let her body remain in the well; fill up the well with earth. Out of her flesh and bones will grow a tree, which shall be called, after her, 'Posto;' that is, the 'poppy tree.'" From this tree will be obtained a drug called 'opium,' which will be celebrated through all ages, and which will be either swallowed or smoked till the end of time. The opium swallower or smoker will have one quality of each of the animals to which Postomani was transformed. He will be mischievous, like a mouse; fond of milk, like a cat; quarrelsome, like a dog; filthy, like an ape; savage, like a boar; and high-tempered, like a queen."

The Precariousness of a Physician's Income.

The following very true remarks we read in the *London Med. Times*, January 10, 1885:

No profession suffers more than ours from the financial pressure incident to sudden failure of health, to accident and to misfortune occurring in the course of a professional career. The medical man, unlike the trader, must earn his living with his own brain and his own hands. When he is disabled even temporarily in mind or body, his power of earning leaves him. A great merchant, when his physician expressed surprise at the serenity with which he bore a long-continued illness, answered, "On my sick-bed I have the consolation of knowing that others are toiling for me day and night; manager and clerks working in my office, ships bringing my merchandise over sea to the markets, and sellers earning me money, and keeping my children, even while I lie here disabled." The medical man has no such comfort. For him the suspension of working power means the suspension of earning power. Bodily pain is only too often intensified by mental suffering and financial worry, and the same blow which affects his physical well-being often shatters his prospects in life, and leaves him more or less helpless. Even in temporary emergencies, the

necessity of paying for a substitute at a time when his earnings are diminished, greatly adds to his cares, and tends rapidly to exhaust his resources.

Died from a Whipping.

The following case, which we find in a despatch dated January 31, in one of our lay contemporaries, deserves more than passing notice:

"Josiah McGrath, of Blue Marsh, an isolated portion of Heidelberg township, in this state, came to Reading to-day and reported to the authorities the death of his little daughter from the result of a whipping she received from her school teacher. The little girl was six years old, and was puny, having just recovered from a severe attack of scarlet fever. The teacher is a big, burly, strong fellow. Mr. McGrath says:

"'My little girl received a whipping in school in the afternoon, just before it closed for the day. When she came home I examined her back, and found on it three large and heavy black and blue welts, as if made with a thick instrument. There was also a mark on her chin, where she said the teacher had struck her with a whip. She told me that the teacher took her by the arm and held her forward against the desk, and struck her with all his might with the whip. When she came home she complained of internal pain. I did not tell her mother, because my wife is critically ill. In forty-eight hours the little one was dead. The heavy welts are still on the dead body of the little one.'"

The Abuse of Alcoholic Liquors.

From an exchange we learn that a prolonged discussion upon this subject has been recently carried on in the German Society of Public Hygiene. The arguments advanced were not new, but they were supported by a number of interesting and important facts. Herr Mehlhausen, who closed the debate (which has been continued through several numbers of the *Deutsche Medizinal-Zeitung*), referred to the extended observations which had been made in the Prussian army with reference to the utility of serving rations of schnapps to soldiers when in active service. The experiment had been thoroughly tried by the army surgeons, with the result of their abandoning spirits for tea and coffee.

It was further stated that the majority of cases of frostbite and sunstroke in campaigns were among those who were addicted to strong drink.

It was not the opinion of the Society that such radical measures should be resorted to as had been taken in Maine, but it was suggested that much might be done by improving the quality of spirits and regulating their sale more strictly. As might be inferred, there was no plea for total abstinence.

Two Famous Opium-Eaters.

With reference to the habits of Coleridge and De Quincey, Cornelius Nicholson writes as follows to the *Brit. Med. Jour.*, January 10, 1885:

I had the honor of knowing both Coleridge and De Quincey, and had more or less quaintance with their habits. There was this difference between them as to their opium-eating; De Quincey was systematic to a degree, both when advancing from lesser to larger doses, and after Dr. Scambler's warning, when gradually lowering himself from the fatal quantity he had once reached. But Coleridge took his opium by fits and starts, as he did everything else, occasionally in such excess as to render him *hors de combat*. Take this incident for an illustration: Dr. Dibdin says he walked through sleet and snow to hear one of Coleridge's lectures on Shakespeare at the London Philosophical Society, and the lecturer never appeared. He had taken an unusual quantity, and forgotten all about the appointed lecture. When eventually the members of his family placed Coleridge as a boarder with James Gillman, a medical practitioner at Highgate, this man judiciously reclaimed the "old man eloquent" from opium-eating.

Philadelphia Clinical Society.

Stated meeting, January 23, 1885. The annual election of officers resulted as follows:

President—Dr. Edward E. Montgomery.
First Vice-President—Dr. John B. Roberts.
Second Vice-President—Dr. Amy L. Barton.
Corresponding Secretary—Dr. Ida E. Richardson.
Recording Secretary—Dr. I. G. Heilman.
Reporting Secretary—Dr. Mary Millik.
Treasurer—Dr. L. Brewer Hall.
Councillors—Dr. James B. Walker, Dr. Daniel Longaker, Dr. Clara Marshall, Dr. Henry Beates, Dr. Henry Leffman.

Items.

—Darwin says there is a living principle in fruit. Does he refer to worms?

—In the *Med. Press*, January 7, 1885, Dr. W. F. Smart reports a case of bullet-wound involving right lobe of liver, with extraction and recovery.

—A young woman of Weymouth, England, recently committed suicide by taking three bottles of chlorodyne. The jury recommended that chlorodyne should be placed among the poisons not saleable except upon prescription.

—The rage for sanitation has spread even to the little kingdom of Servia, which country has sent a commission to England for the purpose of inquiring into and inspecting the various systems of drainage, water-supply, disinfection, etc.

—In the *Lancet*, November 29, 1884, Dr. Sinclair reports a most violent case of acute chorea, in a boy aged twelve years, the result of fright, associated with night screaming and incontinence of urine, that was entirely cured by conium juice.

—In the *Lancet*, October, 1884, p. 669, honey is suggested as a good vehicle for the administration of quinine to children. If the alkaloid be placed in the centre of a small spoonful of honey, the strongest aversion to the flavor will be entirely overcome.

—Dr. L. A. Malone contributes to the *Archives of Pediatrics*, January 15, 1885, a case of hemorrhagic measles, complicated with broncho-pneumonia, supra-orbital abscess, purulent ophthalmia, perforation of the cornea, metastatic abscesses, and spontaneous gangrene: death.

—To avoid as far as possible risk of infection in surgical procedures, Professor Esmarch is stated by the *St. Petersburger Med. Wochenschrift* to have discarded wooden operating-tables and to employ only those made of metal. All the instruments used are nickel-plated and metal-handled.

—Dr. Morgan Hughes (*Brit. Med. Jour.*, January 3, 1885,) has succeeded in relieving severe toothache by the application of a ten per cent. solution of hydrochlorate of cocaine in oil of cloves, applied freely by means of pledgets of cotton-wool, both to the pulp-cavity and to the gums.

—To prevent rapid decomposition of corpses the *Deutsche Medicinische Zeitung* (*Pharmaceutische Centralhalle*), July 17, 1884, suggests washing them with a one per cent. solution of corrosive sublimate, and fitting up the interior of the coffins with wood-wool saturated with the same preservative.

—It is announced that the synthesis of saccharose has been accomplished by MM. Aubert and Giraud, and it is anticipated that the discovery may eventually be of vast importance to the sugar industry. The amylaceous matter of the potato is first converted into glucose and then exposed to the action of a strong electric current.

—The following deaths have been recently announced: Dr. von Wittich, lately Professor of Physiology in the University of Königsbreg; Dr. Karl Vierordt, lately Professor of Physiology in the University of Tübingen; and Dr. F. Chvostek, of Vienna, well known for his researches in electro-therapeutics.

—In the *British Medical Journal*, January 3, 1885, Mr. Blaker publishes the case of a woman, aged about fifty, on whom he had performed lumbar colotomy thirteen months previously, on account of rectal epithelioma. She had gone about without further trouble from the cancer until quite recently; and he had similar, if not better results, in three out of five cases.

—According to *Mittheilungen über Landwirthschaft*, vaseline is a good preservative for eggs. The eggs should be thoroughly washed, and rubbed in with vaseline previously melted with three-tenths per cent. of salicylic acid. The operation should be performed twice, the latter one month after the former. On boiling, the skin of vaseline easily separates from the eggs. Eggs thus treated are said to keep perfectly fresh for a year.

—Dr. Clement Godson reports (*Brit. Med. Jour.*, January 3, 1885,) that he has performed two operations for the removal of vascular growths from the meatus urinarius, after having twice painted the growth, and the area surrounding its attachment, with a twenty per cent. solution of cocaine, seizing it with forceps, and cutting it off with curved scissors, and on neither occasion was anything felt by the patient.

—In the *Ejened. Klin. Gazeta*, No. 13, 1884, p. 236, Dr. Bragin, of the Life-Guard Finland Regiment, describes eight cases of erysipelas treated by painting, three times daily, with five per cent. solution of trichlorphenol. The painted parts were kept covered with a thin layer of hygroscopic wadding. In all the cases, after several applications, redness and tension had diminished, and the spread of erysipelas became slower. From fifteen to eighteen paintings were usually sufficient to cure the disease.

—From the *St. Louis Med. Jour.* we learn that Dr. Seeseman, in the *Petersburger Medicinische Wochenschrift*, states that a corpse may be made to retain the natural form of expresssion for months by (*a*) injecting into it a solution consisting of four to five per cent. of *aluminium chloride* dissolved in a mixture of two parts of *alcohol* of ninety per cent. and one part of *glycerine;* (*b*) painting the entire epidermis with *vaseline.* The quantity of liquid required for injection is in the proportion of one tenth to one-seventh of the weight of the corpse.

—At a meeting of the Suffolk Medical Society (*Boston Medical Journal*), Dr. Graham read an account sent him by a patient, of eighteen fractures he had sustained during the past eighteen years of his life, these being all which he could distinctly remember. Writing fourteen or fifteen years after that age, he had met with no additional fracture. Of the eighteen fractures, nine occurred in the right arm, two in the left arm, three in the left leg, two in the right leg, and one in each collar bone. His father broke his bones fourteen times, and the father's cousin twenty-one times, the father's paternal uncle being also a "bone-breaker."

—M. Ricord, at a recent meeting of the Académie de Médecine, made what he described as a confession of faith. He had witnessed all the epidemics of cholera, the first, in 1832, included. At that moment there were 600 patients in the hospital where he was physician. Not one of these 600, either before the entry or during the residence of the cholera patients, was attacked with cholera. Not one of the nurses, male or female, nor of the medical officers, caught cholera. Dr. Ricord adds that, during this epidemic, he did not see any facts which led him to believe that cholera is contagious. His conviction remains the same after studying the subsequent epidemics, and he is strongly opposed to quarantines, which are irksome and useless.

QUERIES AND REPLIES.

MESSRS. EDITORS:—

What is the difference between the diploma of L. R. C. P. E., L. F. P. & S., Glasgow, and the M. D. granted by the best medical schools of this country? Are they not equal in point of merit, medical scholarship, and the right they bestow on those who hold them, to practice medicine in this country? An answer will greatly oblige MEDICUS.

Answer.—Yes, for all practical purposes the degrees are equal.

MESSRS. EDITORS:—

Can any reader of the REPORTER give me a reliable remedy for acne rosacea, or acne pustulosa? J. T. B.

MESSRS. EDITORS:—

Who uses the irisin comp. pill, the formula of which, as given by the manufacturers, is—

℞.	Irisin,	gr. ¼.
	Podoph.,	gr. 1-10.
	Strych.,	gr. 1-40!

And what is the pill used for? A little definite information would help an INQUIRER.

ORIGINAL DEPARTMENT.

LECTURE.

CLINICAL LECTURE ON DISEASES OF WOMEN, DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROF. T. GAILLARD THOMAS, M. D.

Reported for the MEDICAL AND SURGICAL REPORTER.

REPEATED PREMATURE LABOR FROM PROBABLE FATTY DEGENERATION OF THE PLACENTA.

GENTLEMEN: The case which I now bring before you is one of unusual interest, and the history which the patient give of herself is a very sad one. Her name is Mrs. Elizabeth L——. She was born in the United States, is twenty-two years old, and has been married four years. She has given birth to four children, but every one of them has been still-born. The account that she gives of them is as follows: None of them were born at full term, and the period of gestation at which labor occurred in the four cases was respectively, seven months, six and a half months, eight and a half months, and eight months. Unfortunately, in these various confinements she was attended, not by a regular physician, but by a midwife, but neither the midwife nor herself ever noticed that there was any diseased condition or peculiar appearance about any of the dead children. The patient has always enjoyed good health; and this is the whole history of the case, with the exception of the fact that she is now four months pregnant again; in consequence of which she applies to us to see if medical science cannot do something to prevent the recurrence of the melancholy termination of gestation, which has hitherto continually marred her married life. This is the problem which we have presented to us to solve, and it is certainly one worthy of our most careful attention.

In the early part of pregnancy there are, setting aside accidents, two great causes which, almost without exception, account for miscarriage. These are syphilis and retroversion or retroflexion of the uterus. For premature labors there are also two prominent causes, viz., syphilis and fatty degeneration of the placenta; the latter occurring without any assignable reason. Laceration of the cervix comes under the category of accidents, and barring out this class, I know of no other cause. In such a case as this, therefore, you should always examine the patient with the greatest care for specific disease. Here, however, the woman has not the slightest indication of any syphilitic trouble about her, and, as far as we are able to make out, the husband also seems entirely free from any such suspicion. The history of these repeated premature labors points plainly, then, to fatty degeneration of the placenta as the cause. We have no means of finding out with absolute certainty at present, as, of course, this could only be demonstrated by a microscopical examination of the placenta; but there is, as we have seen, no other cause, except syphilis, that would satisfactorily account for the history.

If we had found the history or symptoms of syphilis, we would place the patient at once on anti-syphilitic treatment. The method which I prefer in such cases is that by inunction, and the

preparation which I am in the habit of using is the ordinary mercurial ointment, which is to be rubbed now into the axillæ and now into the groins and inner surface of the thighs. The husband should also be put through a regular course of anti-syphilitic treatment if there are any indications of the disease about him.

Fatty degeneration of the placenta, in my experience, occurs without any assignable cause, and usually in women who are apparently in most excellent health. When there is reason to suspect the presence of this condition, there is but one thing that can possibly save the life of the child, and that is the induction of premature labor. In the present instance, therefore, when the child in utero gets past the seventh month, it ought to be delivered at once. In the past only one child out of the four has died as early as six and a half months, and so there is every prospect of saving this one. When there is fatty degeneration of the placenta the mother can tell when the fœtus is about to die on account of the diminished activity of its movements. In about a week from the time this is first noticed the movements will cease altogether, unless labor is brought promptly on in the meanwhile, and the child will have died of apnœa, due to an inadequate supply of oxygen. The induction of premature labor is now no longer a doubtful process but a perfectly certain one, and attended by no more danger than parturition at full term. In fact, there is even somewhat less danger than in normal labor, on account of the smaller size of the child's head. As to the exact time at which labor should be brought on in this case, that must depend somewhat on the condition of the child, as indicated by the fœtal movements. If the child seems to be growing feeble at seven months, I would advise that it should be done then; but if there were no such indications, I would wait till seven and a half months, when the operation should certainly be performed under any circumstances.

The method of inducing premature labor which I now invariably adopt is a very simple, and, at the same time, a perfectly efficient one. The patient is placed across the bed, with the buttocks resting near the edge, and under her is arranged a large piece of rubber or oil-cloth in such a way as to drain into a tub below on the floor. In this tub we put one or two gallons of water of a temperature of 98°. The operator stands between the thighs of the patient, whose knees should be be properly supported, and employing a syringe with a long nozzle, which is carried up as far into the cervical canal as it will go, he keeps up a steady stream directly against the membranes. In the course of ten minutes the os will be the size of a silver half-dollar, and when dilatation to this extent has been accomplished, he is to insert a gum catheter between the membranes and the uterine walls. The patient is then put in bed, and that is all.

It may be asked whether, when there is fatty degeneration of the placenta, there is any kind of medicine which, if given to the mother, is capable of prolonging the child's life. In this condition Sir James Simpson was in the habit of administering chlorate of potash, on account of the large amount of oxygen which it is known to give off when taken into the system and decomposed. There is, at all events, no harm in trying this plan, as the drug can be given in very large doses with impunity. It is perfectly safe to give it in drachm doses; but I would not advise its being carried beyond this. It is well-known that a medical man of this city unfortunately lost his life by taking an ounce of it at once, in order to demonstrate in his own person that no bad effects resulted from its use even in enormous quantities. In some cases that have been under my observation, the drug really seems to have facilitated the process of oxygenating the fœtal blood. It should never, however, be relied upon as a substitute for the induction of premature labor. This operation constitues one of the greatest advances that have ever been made in the obstetric art, and it is certainly no mean triumph to be able thus to preserve a human life which, without its aid, would have been inevitably lost. I can point to at least two dozen children in this city, who by this means were saved from an untimely fate. When the infant has been delivered before full term, it should not be washed and otherwise treated in the ordinary manner of nurses, but should be carefully wrapped in warm cotton and allowed to remain in it; the temperature of the room in the meanwhile being brought up to nearly one hundred degrees.

Chronic Slight Cystic Degeneration of the Ovary.

Our next patient is Mrs. Catharine D———, a native of Ireland, and 28 years of age. She has been married four years, and is sterile. The history which she gives of herself is as follows: For more than three years she has suffered constantly from very severe backache. This backache she also had before her marriage, although it was at that time much less severe. She also suffers very

greatly from dyspareunia, or painful cohabitation; and that is all the history of the case. It is quite enough, however, for the patient; who, although not well before her marriage, has had this constant back-ache, which she represents as most intense, while sexual intercourse is so painful to her that it renders her life wretched.

Before I made a physical examination in this case I expected to find the condition known as vaginismus, or spasm of the vagina; but so far from this, I found that the vulva was quite large and the vagina open. There was, then, nothing wrong about the vagina; but just back of the cervix I found a round, hard mass, which was exceedingly sensitive to the touch, and which, the patient at once stated, was the seat of the intense pain which she felt during intercourse.

I have neglected to mention that the back-ache of which she complains, is always aggravated just before and during menstruation, and she told me also that it was here that this pain, too, was located. The uterus was found to be movable and perfectly normal in every other way.

But why should this sensitive mass behind the uterus render the woman sterile? Because it is the ovary, and in a diseased condition. There can be no question that it is the ovary, for if it were a fibroid it would not be entirely disconnected with the uterus, as this is; and it cannot be a phlegmon, the result of peritoneal inflammation, because it is perfectly movable. A hard mass of fæcal matter in the rectum could not be as sensitive as this body is, and it is not a retroflexed uterus, since the probe shows the position of the uterus to be normal. It is, then, an enlarged and diseased ovary which has fallen down into Douglas's *cul-de-sac;* and there can be little doubt that it is a cystic degeneration of the organ which has caused all the trouble. The sterility is in all probability to be accounted for by the fact that the other ovary is in the same diseased condition; although it still remains in its normal position. In a similar case (with the exception of the sterility, the other ovary probably not being affected in that) in which I removed the enlarged and prolapsed ovary, it was found that the whole organ was full of cysts, the average size of which was about that of a gooseberry.

The diagnosis here is, therefore, chronic slight cystic degeneration of the ovary. I have only one remedy to suggest, and that is the cutting through Douglas's *cul-de-sac* and the removal of the prolapsed ovary. I should then pull the other one down and examine it, and if it were found to be healthy in appearance, push it back again. As I have said, the probabilities are that it is diseased also (on account of the sterility of the patient), and if this were found to be the case, it should, of course, be removed in the same way.

We will thus cure the dyspareunia and the backache; and, as for the sterility, it will not be any more hopeless than it is at present, if both the ovaries are in this condition.

Laceration of the Cervix Uteri and Perineum, with Anteflexion of the Uterus.

Our last patient to-day is Mrs. Elizabeth H., a native of the United States, and 32 years of age. She has been married four years and has had three children. The last was born four years ago, and she has never been pregnant since. When I ask her how long she has been sick, she replies, ever since her last child was born.

As we go on in our course you cannot but be struck with the fact that the affections peculiar to women are very commonly traceable to childbirth. If the patient does not say that her trouble commenced at the time of the birth of her last child, she will be pretty sure to date its origin at the time of her marriage.

There is too often, unfortunately, very good reason for this, as these troubles are exceedingly apt to be due primarily to specific inoculation by gonorrhœa, and that without any special culpability on the part of the husband, who may have supposed himself to be entirely free from the disease for six months before marriage.

The principal symptom of which this patient complains is pain in the back and in the region of the right ovary. She also suffers at times from pain in the head and through the eyes. The menstrual function is performed regularly, and without difficulty, and she says she has no leucorrhœa. She can walk about and stand without suffering, as a rule, but cannot lie on the right side in bed, on account of the pain just mentioned.

The examination *per vaginam* revealed a badly-lacerated cervix. There can scarcely be a doubt that this occurred at the time of the labor four years ago (although the patient says she had no special difficulty then, and was not delivered with instruments), as she has never enjoyed good health since, and has never been pregnant since. But this was not all that I found. The perineum, which had, no doubt, been torn at the same time, was lacking, and the fundus of the uterus, instead of being in its normal position, was found to have fallen forward over the bladder in consequence. Although the patient said

she had no leucorrhœa when questioned on the point, there was found a copious discharge of this character, as one would naturally expect with the condition of the parts that is here present. I might here pause to say that a patient's denial of the fact that she has leucorrhœa is of no value whatever, and should never be trusted. Why women should say they don't have it when they really do, is more than I can tell; but it is a fact that this is not infrequently the case.

At the time of the last labor, then, the cervix was torn, the perineum was lost, and the enlarged and weighty uterus, deprived to a great extent of its natural support, settled forward in its present position. As a result, there followed a chronic state of congestion in the endometrium, which continually pours out an ichorous secretion so acrid as to cause vaginitis. The correct diagnosis is, therefore, as follows:

1. Laceration of the cervix.
2. Rupture of the perinenum.
3. Anteflexion of the uterus.
4. Resulting vaginitis.

This is a well-marked and closely-connected pathological series, and in such cases, where the diagnosis is a somewhat complex one, we should always be very careful to take up the links of the chain in their proper order.

I have but a moment left now for the subject of treatment. Where shall we begin to correct this series of evils which have just been enumerated? The first thing to be done here is to straighten up this anteflexed uterus, and this is not to be accomplished by putting in a pessary, for I do not believe that the patient would at present be able to wear one. The best plan will be to introduce a sound two or three times a week and bend back the uterus, which is perfectly movable. Of course, at first it will always return to the abnormal position to which it has so long been accustomed, but gradually through the agency of this course of gymnastics, as it may be called, the organ will become straighter and straighter, until it has at last resumed its natural position. In the meanwhile, constant treatment by means of hot douches, etc., should be kept up for the relief of the uterine congestion. The next step in the cure will be the closure of the lacerated cervix, and, finally, the restoration of the perineum should be made.

(*To be continued.*)

—In asthmatic affections Prof. Bartholow says the inhalation of iodide of ethyl is of great utility.

Communications.

SOME OF THE COMMON DISORDERS OF INFANCY AND EARLY CHILDHOOD.

BY G. A. HILL, M. D.

(*Continued from page* 166.)

When these conditions are present there is strong presumptive evidence of the near approach of a fit, and if seen at this time by the physician he should promptly seek out the exciting cause, and as promptly remove it. If the gums are swollen and tense they ought at once to be incised, and not only the gum but the peridentine, the tense state of which, from the advancing tooth, may be the real cause of the trouble. Superficial scoring of the congested gum, though offering some relief by the depletion, is not sufficient. Sometimes an emetic given at this time may so relax the system as to avert the spasm, and thus give time for the use of more rational means directed to the causation; indeed, if the fit be imminent, there is scarcely any measure we can rely upon with so much certainty.

If the child is seen during the seizure, nothing will act more satisfactorily in bringing about relaxation and repose than a warm bath up to the neck, or if preferred, the hot pack, assisted by a little chloroform if need be.

After the convulsion has subsided, he will pass into a state of limp lethargy, only to be followed, probably, by others in more or less rapid succession.

Before going further, it should be ascertained, if possible, whether he has been the subject of any recent acute disease, if the stomach and bowels have shown disturbed function, and whether there has been noticed a twitching of the hands and feet for any length of time prior to the first fit. In general it may be stated that a rapid pulse, with slight feverishness, vomiting, and diarrhœa, denote functional or peripheral irritation, and is best met by a mild but brisk cathartic, followed or not by bromide of potassium, belladonna, or assafœtida, to allay reflex nervous irritation. We have in the bromides a powerful remedy for the control of infantile eclampsia, but to be of good service they should be given in relatively large doses, five or six grains of the potassium salt being easily borne by a child a year old. As soon, however, as the physiological effect has become fairly manifest, the dose should be diminished, or the drug discontinued. The indiscriminate use of the bromine salts is as fatal to the

well-being and future development of the child as their judicious employment is beneficial. I have thought sometimes that in this age our little ones are not unfrequently the victims of *fashion* with respect to this drug.

There are many causes of convulsions and conditions favorable to their development which I have not even the space to name. I will mention one, however, as having been given by the older writers, and at least not denied by the author of a recent article. This is the drying up of suppurating surfaces, as sores behind the ears. I confess to be very incredulous on this point; at least I have never hesitated in advising measures for the removal of these annoying and unsightly disfigurements, and have never seen any ill effects therefrom.

Vomiting is another trouble frequently met with even in children otherwise quite healthy. However, as a recurrent symptom in more severe affections, it should occupy our serious attention. It is well known as a precursor of that terrible disease, tubercular meningitis, as also of some exanthems, as scarlatina, etc. When the stomach is overloaded, or has been irritated by undigested food, its evacuation is rather to be considered a fortunate propensity than as a sign of disease; but if this irritability continues, and the child shows signs of exhaustion or inanition, it becomes necessary to interpose medical aid. His food, if the child be fed artificially, must be changed; this change is frequently productive of good results, even when the diet adopted has no special superiority over that laid aside. The little stomach seems grateful for the change, and at once ceases its revolts. For infants a mixture, of equal parts of milk, lime water, and arrow-root water sweetened with a little milk sugar, will scarcely ever irritate the most delicate stomach.

The various diastatic preparations, as the extracts of malt, if added in small quantities to the milk will often be found to exercise a happy effect in facilitating the digestive process. Baby foods without number have been promulgated, some of which possess real merit. My experience with Mellin's and Horlick's infant foods has been most favorable to their strong recommendation. If the digestive powers are much impaired from debility or other cause, pepsin should be given with each feeding.

For excessive irritability and vomiting between meals it is often necessary to resort to medicines; the following combination has succeeded so constantly in my hands that I offer it without apology:

℞. Spt. chloroformi, ℥j.
Creasoti (ligni), ♏ij.
Vini ipecac, ♏v.
Aquæ anisi, q. s. ad. f. ℥ij. M.

Sig.—A teaspoonful for a child a year old.

Closely associated with the above, and depending upon similar causative influences is *colic*, which, though not difficult, generally, to relieve, should not be treated lightly, since from the pain, loss of rest, and other strains upon the nervous system convulsions may supervene.

Usually, to one accustomed to note closely the actions of his little patients, there should be no difficulty in determining in this instance the cause of the distress. In simple, spasmodic colic, the contracted brow and screwed-up mouth, the loud, angry cry, and the hard, nodulated abdomen, are, during the paroxysm, the characteristic symptoms; there is also, I think, a slight elevation of temperature. Sometimes there is diarrhœa, but generally the bowels are costive, with a reversed peristalsis, causing vomiting of bilious matter.

Of course, the first thing is to relieve the pain by anodynes, if it seems violent, for which a mixture in equal parts of those time-honored remedies, elixir paregoric and Hoffman's anodyne, can scarcely be improved upon. After this, a mild cathartic is clearly indicated, or what may be better, if vomiting has commenced, an enema of castor oil. The old plan of giving emetics in such cases, while probably effectual in relieving intestinal spasm, I would consider too prostrating and for this reason do not prescribe them. When there is intestinal dyspepsia, as indicated by milk-curd or other undissolved matter on the napkin, some of the modern digestives, with or without the so-called carminatives, are proper; a little tincture of assafœtida, with the well-known elixir lactopeptine, are excellent for this purpose, especially in very young babies. Attention should likewise be had to the constitution, usually found faulty in these cases, by inaugurating better food, better hygiene, and tonics.

I beg to speak briefly of one other difficulty, which, though not frequently dangerous, is very annoying to both infant and parent, and occasionally so distressing as to seriously compromise the health of the little victim. I allude to *excoriations*. Improper dressing, want of strict cleanliness, diarrhœic or acid stools, excessive delicacy of the skin, and unwholesome food, are the common causes of this affection. By this constant peripheral irritation the child becomes extremely nervous, starting and crying in his sleep, restless and petulant, and in other ways showing a

highly perturbed nervous state. Should these things continue, local nutrition may become so modified as to cause the abrasions to take on unhealthy action, and may even degenerate into sores, having no tendency to heal spontaneously. By removing probable causes, giving alkaline laxatives or correctives, improving nutrition, and the use of appropriate local measures, there is usually no difficulty in curing the trouble. Locally, I have found equal parts of rice flour and subnitrate of bismuth, with a little morphia, to answer well. Oleate of zinc may take the place of the bismuth. Soap and water should also have an honored place among the best of local remedies.

A CASE OF PUERPERAL FEVER DUE TO AUTO-INFECTION.*

BY L. N. DAVIS, M. D.,

Of Farmland, Ind.

September 8, 1884, at 7 a. m., saw, with Dr. K., Mrs. C., aged 28 years, in her first confinement. She had a miscarriage about two years ago, since which time she has been more or less bloated, troubled with indigestion and frequent pains in the pit of the stomach, attended at times with burning sensation. Digestive disturbance, however, has never seriously interfered with her appetite or nutrition; nor has she suffered sufficiently at any time to seriously molest her in the discharge of her ordinary household duties. Found much œdema of the face, as well as of the upper and lower extremities. Has been in labor for five or six hours, and seems very apprehensive as to the result. Pains seem rather "niggling," as the old English nurses would put it, and not very effective in furthering labor, but rather adding to her general distress, in the shape of dyspnœa, headache, and nausea. Examination revealed os considerably dilated, waters discharged, and a breech presentation, with hips slightly engaged in the superior strait. Suspecting albuminuria, with impending eclampsia, we gave a small dose of morphia, and succeeded it with an occasional dose of chloral and bromide of potash, for the purpose of improving the pains, as well as allaying the nervous perturbation. Assuring the doctor that there would not likely be any obstacle to the natural delivery of the woman, I left in discharge of my routine duties. Later in the day, on account of increased alarm, Dr. R. was called to the assistance of Dr. K. Labor was terminated by the natural efforts about 9 p. m., in the hands of Dr. R., with a still-born child of medium size.

I heard nothing more from the case for four or five days, when Dr. K. invited me to see it again. Has had one or two chills; has loss of appetite, with nausea and vomiting; slight looseness of the bowels, discharges dark and offensive; retention and almost suppression of the urine, not exceeding two ounces being secreted in the past twenty-four hours; of very dark color and heavily charged with albumen. Complains of lancinating pains from pit of the stomach through to the shoulder blades; also pains of less intensity over the entire abdomen; lochial discharge about normal in quantity; lacteal secretion very scanty; dark red flush on the cheeks, and whitish-yellow fur on the tongue. Bowels tympanitic, with diffused tenderness. Pulse, 100; temperature, 104; respiration, 32. She was given mucilaginous drinks, light doses of aconite and digitalis, and fomentations containing digitalis were applied to the loins. Under this treatment, the urine increased to quite the normal quantity, but still requires the catheter for removal.

Improvement in all other respects also followed in a few days, except in the condition of the stomach, the functions of this organ seeming to grow worse, if any difference; increased difficulty in retaining nourishment, with frequent eructations of bile mixed with mucus and blood, occasionally becoming dark and assuming the "coffee-ground" appearance. Diarrhœa and constipation alternating, but neither being characteristic features of the case. Discharges from bowels evidently contain blood in small quantity. Vaginal washes have been used, though not assiduously. We now ascertained that there was marked laceration of the perineum.

At this juncture Dr. R. was again called in to see the case, and soon assumed regal sway, for he was little opposed, presuming, as we did, that he was looked to as the medical director. He seemed to be infused with but few modern medical ideas, and none more than the "specific medication" phantasy. He declared that several agents were indicated by the peculiar shape, color, and secretion of the tongue, but more than all else the specific tincture of "apis." As he seemed to have a penchant to prescribe for the tongue, and we, the patient, concord of sentiment was out of the question, and was only apparently maintained to preserve the decorum of the sick-room, which I hold to be of paramount importance to all technicalities in similar cases.

Later in the case (I learned), during a term of

*Read before the Delaware District Medical Society.

constipation, he conceived the idea that the tongue indicated colocynth, and none of the fluid extract being obtainable, he told his druggist that fluid extract of colchicum was tantamount to colocynth, and therefore he would administer the colchicum. Two or more five-drop doses of the fluid extract of colchicum were given in this critical case of septicæmia and uræmia, with ulceration of the stomach existing as a local admonition to stay medication and give the organ a little much needed repose; given at a time when a straw in the path might decide the fate of the patient. Whether it had any unfavorable effect on the case or not, I am unable to say, but certainly it was contraindicated by any line of logic which we usually apply in such cases.

It will be clearly understood, from the details of the above case, that it was wholly due to intrinsic causes; and yet it was none the less a typical case of so-called child-bed fever. I have not the *least* doubt that more than one cause entered into its composition, namely, the pre-disposing cause consisting of albuminuria, with all that it involves, and gastric ulcer; the exciting cause being septic poison induced by *auto-infection*. That any one of the causes would have been sufficient, with the ordeal of confinement, to have developed a full-fledged case of puerperal septicæmia, I have my most serious doubts; all taken together, it was inevitable. I have no hesitation in excluding, as a possible cause, contagion or infection arising from any source, that, mayhap, the poison of child-bed fever could issue, external to the body of our patient: Because 1, child-bed fever, of whatever origin, is of very rare occurrence in this section; never, indeed, did it prevail epidemically in the history of the country; hence it could not have been due to a special germ, like zymotic fevers, as claimed by Fordyce Barker, and other eminent authorities; neither do I believe that puerperal fever, as the term is generally used, *has a special cause*. Because 2, if child-bed fever owes its origin to the causes of surgical septicæmia in general, as claimed by Burdon-Sanderson, then it must have had its origin within the patient, for no surgical or other cases existed, from which such poison could have been transmitted. Because 3, if child-bed fever be due, in any case, to infection from other zymotic diseases, as admitted by most of European authorities, and as I verily believe to be true, ours could not have had such cause—for no scarlatina, diphtheria, measles, or other zymotic fever prevailed.

The post-mortem appearances of subjects of puerperal fever seem to be in nowise constant. In some of the most intense and malignant cases, indeed, the pathology is entirely wanting; while in others of a less severe type, it varies from a local inflammation of the peritoneum to the involvement of almost every organ and tissue of the body. Why then should we record all cases of childbed fever as of similar origin? It seems to me that nothing could be more derogatory to our common sense. And yet it is obvious that many authorities contend for a special cause to the exclusion of all others. If they could but take a broader and more liberal view of the etiology of diseases in general, but more especially this one, less confusion would certainly prevail in the medical world, and more accurate and careful observation would be made. In this view I hope I am not pessimistic, neither do I claim to be optimistic. But of one thing I feel sure; and that is, if we rely upon a few men to make observations for us, we will always be in ignorance and confusion. Medicine is not so much of a science that it can be solved to a mathematical certainty. Every physician, to a certain extent, must make his own observations and collect his own data; for according to his capacity, facilities, and habits of industry, he is authority on the many unsolved problems of medicine.

If Mrs. C. had not been a sufferer from chronic Bright's disease, she would perhaps have escaped septicæmia; if septicæmia had not originated, I have but little doubt that she would have gotten through her confinement with the nephritic disorder and gastric ulcer. All physicians whose observations have extended over many years will concur, that the tendency to child-bed fever, as well as other serious complications, is very great in cases of confinement coëxistent with albuminuria; and that it is only with the most careful attention that many such cases escape with their lives.

In the cases of albuminuria in which child-bed fever has supervened that have come under my notice, I have had but little doubt that self-infection, as in the above case, from lacerated perineum or cervix, constituted a prominent factor in the causation.

In conclusion, I feel warranted in saying that the cases constituting the class of disease called puerperal fever do not owe their origin to one, but many causes, and only deserve a special name to designate a class into which almost any case of fever succeeding confinement may be placed. It would certainly be a wise and happy hit if the term, as it is generally used, could be expunged from our text-books. It does not imply a special train of symptoms, call for a special line of treat-

ment, involve a definite cause, or necessitate a peculiar pathological condition; hence the only propriety that can be claimed for its use, is that it denotes a fever during the lying-in state. It is quite true and reasonable that two fevers of adverse nature, occurring at such a time, may, and will, assume symptoms in common, and that both will present symptoms peculiar to the puerperal state; and, further, that they may be so nearly identical as to render it entirely impossible to distinguish between them. I can easily understand how almost any fever occurring during the lying-in state may be diverted from its regular course, and obscured by local and general symptoms peculiar to the state of the patient, to such an extent as to lose, not only its identity, but its pathological expression as well. I sincerely believe that child-bed fever may have the same identical cause as surgical septicæmia, phlegmonous erysipelas, scarlatina, diphtheria, and doubtless, also, as measles, typhus and typhoid fevers. Other causes are also quite possible, in my mind; but the causes to which we can most frequently attribute our cases through the country are those of predisposition and auto-infection.

Hospital Reports.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY WILLIAM GOODELL, M. D.,

Professor of Gynæcology in the University of Pennsylvania.

Reported by William H. Morrison, M. D.

Multiple Fibroid Tumors, Removal by Abdominal Section; Recovery—Oophorectomy—Injury to the Urethra, the Result of Dilatation—Vesico-vaginal Fistula—Operation.

Gentlemen: To-day I shall occupy the hour in showing you the results of some of the operations which have recently been performed.

The first case which I shall have brought in is the woman from whom the multiple fibroid tumor that I now show you was removed. After removal this growth weighed thirteen and a half pounds. It undoubtedly weighed more, for a large portion of the blood which it had contained had escaped. You see what a conglomeration of tumors it is. The operation was performed about three weeks ago. Only on one occasion was the temperature above 100°, and that was on the day following the operation. The tumors were firmly attached to the intestines and the wall of the abdomen, requiring dissection with the knife. The pedicle of the tumor was as large as my arm below the biceps. This was encircled at first with the ordinary ecraseur, which was drawn as tight as possible without cutting the tissue. A smaller wire ecraseur was then passed and allowed to remain, the pedicle being transfixed with wires. It was sixteen days before the clamp came away. A deep cavity was left in the wall of the abdomen.

The removal of fibroid tumors has been a most fatal operation, but with the modern methods of operation, the success has been greater. Dr. Keith, of Edinburgh, and Dr. Bantling, of London, have been extremely successful with this operation. In this country the results have not been so good. Why this is I am not prepared to say, for all the details of antiseptic surgery have been adhered to.

In the present case the ovaries and the womb were also removed, the wire ecraseur being placed low down on what should have been the cervix of the womb, but which was enlarged to the size of the arm. For the first week, the odor from the stump was pretty bad, and poisoned the room in spite of all that could be done. The part was kept clean, and dressed with salicylate of sodium.

Although fibroid tumors of the uterus are very common, it is fortunately rare that the operation is required. Usually the affection shows itself late in life, and we are able to control the bleeding until the occurrence of the menopause, which in these cases does not come on until a later age than usual (about fifty). To control the disease, we administer chloride of ammonium, ergot, and remedies intended to increase the richness of the blood. Sometimes iron does good, while at other times it increases the loss of blood. By these measures the patient can usually be tided over the period until the change of life occurs. After this time, the tumors rarely increase in size, but one of two things occurs—they either remain stationary or diminish in size.

One word about the expression of the face in uterine and ovarian disease. This woman had the facies uterinæ well-marked. In cases of abdominal tumors, there are two, or we may say three, expressions of countenance. In fibroid tumor of the womb, there is a peculiar, anxious expression of countenance, and also a marked discoloration of the face, which becomes dark. There is a deposit of pigment which is almost pathognomonic. In ovarian tumors, there is great emaciation, especially if the disease is advanced. This is not present in uterine fibroid, even if the patient has lost a great deal of blood. There is also in ovarian tumor an anxious expression of countenance, to which the name facies ovarianæ has been given. We may see a third expression of countenance in parovarian tumors which is almost that of health.

Oophorectomy.

This case I also operated on three weeks ago. She is 37 years of age. Six years ago she gave birth to a child. From her history, I infer that at that time she met with two accidents. Shortly afterwards she found that the menses were becoming menorrhagic, and for a week before menstruating she had difficulty in locomotion, with intense bearing-down feelings. She was in a fair condition of health for only one week out of four. She consulted an excellent gentleman in San Francisco, who recognized a laceration of the cervix, which he repaired. This gave no benefit, and she consulted another surgeon, who, finding a tear of the perineum, operated on that. This

did no good. Pessaries of all kinds have been used, but did not influence the bearing-down feeling. She went from bad to worse, and being in poor circumstances and dependent on her friends, she came to me to see if something could not be done for her relief.

She was very pale and thin, and unable to do any work. On examining, I found that the ovaries were excessively tender, and that one was prolapsed and enlarged. Where there is passive congestion of the pelvic organs continuing for any length of time, it may become formative in its character, and instead of a simple congestion, structural changes in the ovaries are produced. In such cases the condition can not be cured until the occurrence of the change of life. There are two forms of degeneration of the ovaries, viz., the parenchymatous and the cystic. The latter may produce ovarian cysts, although I am not prepared to say that such is the case.

Having seen the good results which sometimes follow in these cases under the rest treatment, with electricity, forced feeding, and so on, I did not feel warranted in operating until this had been tried. She was placed in the Orthopœdic Hospital. She returned unimproved, and I decided to remove the ovaries. I operated three weeks ago to-morrow. There was cystic disease of both ovaries. She recovered from the operation without a single bad symptom. There was no elevation of temperature. At no time did it go above 100°. The only trouble resulted from drawing the water. This induced great irritability of the bladder. This was treated with a remedy which is almost a specific in these attacks of irritable bladder, that is a suppository consisting of one grain of the aqueous extract of opium, with from a half to one grain of extract of belladonna. It is necessary to feel the way with the belladonna. These patients will always bear one grain of the extract of opium. The wound healed by first intention from one end to the other. There was not a drop of pus. I believe that we are going to give her a new life, and that as soon as her appetite returns and she picks up in flesh, she will be a well woman, and that the bearing-down feeling will never return.

One word in regard to the operation. It is not an easy one to perform, especially if the woman is fat. When there is a tumor of any size, the tumor comes directly against the abdominal wall, and there is little danger of intestine intervening. In this instance, the intestine came directly against the abdominal wall. Under such circumstances, it requires very careful cutting to open the peritoneum without injuring the in-bowel. After cutting through the outer tissues and controlling the hemorrhage, I catch the peritoneum with a tenaculum, taking the smallest possible hold, and then draw it up so as to be sure to raise it from any intestine that may be underneath. Having done this, I make a delicate nick, and then introduce a director and enlarge the opening. Another difficulty of this operation is that the opening is very small, admitting of the entrance of no more than two fingers. The fingers are passed to the womb and then run along the broad ligament until the ovary is reached. The ovary is then seized with forceps and an attempt made to drag it out. If there are adhesions, the difficulties are still further increased. In such cases, it is a hard matter to get pedicle enough and to be sure that all the ovary has been removed. I believe that in many instances in which the ovaries have been supposed to have been removed, that a portion has been left behind, thus accounting for the continuance of menstruation in a few cases. In only one of the cases in which I have removed both ovaries has there been any return of menstruation. That occurred three years ago. I am sure that I removed both ovaries. There may be a third ovary or supplemental ovarian tissue. Nodules of ovarian tissue have been found at a distance from the ovaries. To show you how small a portion of ovarian structure will keep up menstruation, let me relate the following case:

Some years ago, I removed the ovaries per vaginam (and this, by the way, was one of the reasons why I gave up this operation). I removed one ovary without any difficulty, and caught the second ovary with fenestrated forceps, but in pulling it down, the tissue tore, and a large portion came away, but some remained behind. From an examination of the piece removed it was evident that the portion left must be very small. The operation was done for menorrhagia and masturbation, but it did not give entire relief. She finally became so disgusted with herself that she desired me to perform abdominal section. I did so, and found that the portion of tissue left behind was not larger than a bean. That little fragment kept up the profuse menstruation. I am sorry to say that the operation resulted fatally.

To return to the operation: after getting the ovaries out, it is necessary to watch the pulse as you tie the pedicles, for pressure on the ovarian nerves may cause collapse. The pedicle is transfixed with a double thread, and tied in two portions. The ovary is then cut off, and the pedicle carefully examined, to see if all has been removed. When the ovaries are bound down by adhesions it is difficult to get at them, for the opening is small, and the recti muscles become very tense. I look upon this operation as far more difficult than the removal of an ovarian tumor.

Incontinence of Urine Due to Injury to the Urethra. Vesico-vaginal Fistula Operation.

The next case is the one on which I operated last week. As you will remember, the woman had suffered from cystitis, and dilatation of the urethra had been practiced. She states that two fingers were introduced into the canal. Dilatation not being successful, a vesico-vaginal fistula was made. This relieved her very much, but when the opening began to close the old symptoms returned. She then came to me. I made the fistula larger, and syringed out the bladder with a solution of strong nitrate of silver. This cured the inflammation, and I closed up the fistula. She then found that she had no control over the urethra, which had been torn in the operation of dilatation. Two weeks ago I operated on the urethra, but at the same time I told the patient that I feared that the operation would not be a complete success. I was sure that I should

obtain union, but I was not so sure of giving her control over the urethra. The union has been perfect, but there is still constant dribbling. This urethra is not too large, and indeed it is smaller than the average.

Examining the cicatrix of the old vesico-vaginal fistula, I have made a discovery. There is still a small opening there. I shall therefore close up that opening. It may be that all the trouble has come from this, but the patient thought that it came from the urethra. In operating on these small fistulæ a larger opening has to be made. I make an incision on each side, and try to denude the surface without cutting into the bladder. After that operation it has been customary to introduce a catheter, but I shall not do so. I have given up the use of catheters when the opening is close to the urethra, for it is sure to impinge on the part, and is liable to prevent union. Sometimes these fistulæ may be closed by touching them with Paquelin's cautery, but this is not so sure as the cutting operation, for these small openings are sometimes very difficult to close. For closing the opening, I use the finest wire compatible with strength, for the thicker the wire the more liable it is to ulcerate its way through. I enter the needle one-third of an inch from the margin of the wound, try to avoid entering the bladder, and bring it out at a corresponding point on the opposite side. This small opening, which is not large enough to admit a probe, will require two stitches to bring it together. I hardly think that this opening was large enough to account for the free flow of urine from which the patient suffered. The patient will be kept in bed and the sutures removed in ten days or two weeks. Before slipping the shot down over the wire and clamping the sutures, I have some water thrown in to wash away the clots and blood. Securing the stitches brings the edges of the wound into complete apposition.

This condition used to be the opprobrium of surgery. I cannot tell you why it is that we are more successful now than formerly. It is supposed by some that it is because we use silver wire, but one of the best German operators, Simon, of Heidelberg, uses silk. It used to be that when a surgeon had a successful case of operation on vesico-vaginal fistula, he at once sent an account to the journals; but now, success is the rule.

The former practice was to always insert a self-retaining catheter. I have had three cases in which union was undoubtedly prevented by the catheter. One was operated on three times by an excellent surgeon, and each time the fistula failed to unite. The fourth time, I operated and the same thing happened. At the fifth operation, I made up my mind that I should operate without the catheter. That operation was a success. I had another case which had been operated on a number of times by a good surgeon. Finally, she came into my hands, and I operated with the catheter, and the operation failed. Tnere was some uterine tenesmus. I again operated, discarding the catheter, and the operation succeded. I had still another case which had been operated on a number of times by another surgeon. The opening was near the neck of the bladder, and when I operated, I omitted the use of the catheter, and the fistula healed.

In the present case, I operated on the urethra last week, making the orifice smaller. I did not use a catheter, and union has been perfect. When the fistula is higher up, there is not so much danger from the use of the catheter, but even then, as the fistula is always between the cervix and the bladder, there is always a risk that a self-retaining catheter will impinge on the wound and prevent union, as the bladder is always contracted.

[Note.—This patient left the hospital greatly improved.]

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, November 28, 1884, the President, Dr. Henry Beates, jr., in the chair, Dr. Massey, secretary.

Dr. John B. Roberts read the following paper on

"NOTES ON SOME INSTRUCTIVE CASES OF HERNIA."

Hernia is a condition often seen and often improperly treated; therefore, I shall not apologize for bringing a few illustrative cases to the attention of the society, in the hope of stimulating discussion on this important topic.

Reduction of an Irreducible Femoral Hernia of Seven Years' Standing.

Some months ago a woman was sent to me by a medical friend in a neighboring State, suffering with a small, painful tumor in the right groin, which had appeared seven years previously, while she was lifting a heavy weight. The tumor had never been "pushed back," and had of late increased somewhat in size. For its treatment she had recently bought a truss, but could not wear it. When seen by me the hernia was the size of a small hen's egg, was somewhat painful when handled, and occupied the situation of the femoral ring. The truss she brought with her was one for inguinal hernia, and gave pain by pressing on the tumor. After reduction of the hernia was accomplished I found, as was to be expected, that the truss pad did not cover the opening through which the hernia escaped.

I placed her in the recumbent position, in my office, and without difficulty succeeded in reducing the entire hernial protrusion by first pulling the tumor downward, in a direction toward the knee, and then pushing backward, toward the bed. No anæsthesia was employed. A truss made with an inguinal hernia pad and a band passing around the perineum from the pad to the back of the truss-spring seemed to retain the intestine securely within the abdomen. As the patient has not applied for further treatment, I presume that she has had no special inconvenience since.

It certainly is strange that a hernia which had never been returned since its appearance seven years previously should be so readily reduced. Attempts to reduce it had, according to her statement, been previously made, but I know not how often. After I replaced the gut, which I did several times during her stay in the city, I could put the tip of my finger into the femoral ring, thus

showing that the reduction was complete. I am inclined to believe that she had a small, direct inguinal hernia in addition to the femoral hernia, for, after reducing the femoral hernia, which caused the main bulk of the tumor, a small tumefaction was still left, which could be made to disappear by pressure toward the external inguinal ring. On the other hand, I thought I was able to push back this upper part of the mass and hold my finger in the inguinal ring, without affecting the femoral hernia which certainly existed below.

This occurrence of double hernia on the same side is often, I think, overlooked in hurried examinations.

Irreducible Incomplete Hernia.

A man of seventy-seven years, who had a reducible hernia of the right side, sent for surgical aid because he noticed a small swelling in the left groin, which he could not reduce. He told me that he formerly had left side hernia, but had been cured by wearing a truss. He was anxious, because the right hernia had once become strangulated and required manipulation by a physician to reduce it. I saw him late in the afternoon. He lay in bed, with slight abdominal uneasiness, but had had no vomiting, and during the day had had an evacuation of the bowels. The abdominal wall was thin, and above Poupart's ligament on the left side I could feel within the wall a tumor the size of a small black walnut. On coughing, distinct succussion was felt in the tumor, which protruded little or none through the external inguinal ring. The tumor, which was tympanitic, was evidently an oblique inguinal hernia, which had not traversed the entire length of the inguinal canal.

Under ether I attempted taxis, but, though I heard some gurgling in the belly during my manipulations, I felt no distinct slipping of the hernia into the abdominal cavity. The tumor, however, seemed smaller, and by invaginating the scrotum I could introduce my finger half way up the inguinal canal. I concluded that he had previously had a small, incomplete hernia, which had passed unnoticed; and that a sudden increase, with some attending pain, had called his attention to the groin on this occasion.

Accordingly, I prescribed a little morphia and recommended quiet in bed. When I visited him next day, the tumor was entirely gone; and he reported that, shortly after his recovery from ether, pressure by his own fingers easily caused the protrusion to disappear. Some tenderness still remained. He was told to stay in bed two days and then obtain a truss. I have not seen him since.

Recovery from Strangulated Hernia After Refusal of Operation.

Two or three years ago Dr. J. M. DaCosta requested me to see a man who had had left-side hernia for about four years, which was now, and had been for many months, irreducible. For two days and a half the patient had had no stool and had been complaining of pain referable to the hernial and to the umbilical region. Dr. DaCosta had attempted taxis, but failing, had given castor oil, which was vomited without inducing an action from the rectum. An enema was ordered and a subcutaneous injection of morphia given; after which he called me to meet him in consultation. When we saw the patient, he complained of no pain. I was not able to get any accurate history of the case from the man himself or his family, but he had a hernia the size of a black walnut, elongated horizontally, lying apparently below Poupart's ligament. I was unable to determine to my satisfaction whether it was a direct inguinal or a femoral hernia. Taxis under ether failed to reduce the hernia, and as herniotomy, though strongly urged by Dr. DaCosta and myself, was refused, opium and belladonna were administered and ice applied to the tumor.

I did not see the patient again, but was informed, two days later, that abdominal tenderness was somewhat more marked, though there was no pain except on pressure. No action of the bowels had occurred. When I saw the attending physician several weeks after, he said the patient had recovered without showing any further unfavorable symptoms. The hernial tumor, of course, remained.

In this instance the unfavorable prognosis made by me was unsustained by the history of the case. Whether strangulation of a small portion of an old hernia was relieved by the manipulative efforts made by Dr. DaCosta before my visit, or by our joint action, or whether actual strangulation never existed, I was unable to determine. The history, indefinite as it was, and the symptoms, justified resort to operation, because of the well known danger of operative delay in strangulated hernia. In all similar cases I should still advocate exploratory incision.

Herniotomy for Strangulated Femoral Hernia in a Paralytic.

A feeble woman, aged about sixty years, and almost helpless from cerebro-spinal sclerosis, had had for many years hernia in both groins, and wore a truss. The daughter, who had to feed the patient and wait upon her, on account of her paralytic condition, was able to reduce the hernial protrusions when they appeared. On August 18, 1882, at 9 a. m., the hernia at the right femoral ring became irreducible after protrusion. The bowels were opened during the day, and there was nausea, but no vomiting. She seemed, when seen in the evening, to have considerable abdominal pain, but her mental condition and inability to articulate plainly made the obtaining of an accurate history difficult. The tumor, which was the size of a very small apple, was firmly fixed and could not be reduced. After futile efforts at reduction, under ether, I made, about eleven hours after strangulation, an incision, and tore through the coverings with forceps and fingers until I reached the sac. Then I stretched Gimbernat's ligament by forcing my finger tip into the canal, but the hernia was still irreducible, showing that the constriction was probably in the neck of the sac. After sweeping my finger around the neck of the sac and detaching it from the surrounding tissues, I was able to overcome the obstruction to replacement, and easily pushed the gut into the abdominal cavity. The sac was, as is seen, not opened. I believe that I stretched or pulled apart some pleatings or folds at the neck

of the sac, and thus liberated the intestine. After pushing the sac also back into the abdomen, the wound was washed with carbolized water and sutures applied. One of the sutures was a very deep one. No ligatures were needed. The wound healed promptly, with but a single drop of pus. The patient's return to her usual condition was delayed, however, by the occurrence of troublesome diarrhœa.

About eighteen months afterward I saw her. There was then a small hernia at the old site, for which she wore a truss. On the left side I found that the hernial tumor then existing consisted of a large inguinal and a small femoral protrusion. She wore a truss for this tumor, but it did not retain the intestine within the abdomen; but her inability to walk, because of her paralytic state, rendered the wearing of a truss not so essential as in an active person.

I might report other cases of hernia in which I have seen more or less unusual features; for example, a case of herniotomy in a child of six weeks, which I recently saw in consultation with Dr. Steinbach, who operated; or that of a woman with exceedingly large inguinal hernia; but for my purpose of exciting discussion, the cases reported will be sufficient.

I desire to emphasize the following points:

That inguinal and femoral hernia will be found at the same time on the same side much oftener than is supposed.

That it is safer to operate in cases of suspected strangulation than to postpone operation beyond twelve hours.

That herniotomy is attended with little hæmorrhage, and if done antiseptically, is accompanied by rapid union and little risk to life.

DISCUSSION ON DR. ROBERTS'S PAPER.

Prof. James B. Walker: "In connection with Dr. Roberts's paper, a brief narration of the salient points of the following cases may be of interest:

"Case 1. A lady aged 79, as the result of a fall, noticed a swelling in the left groin below Poupart's ligament, in vicinity of the femoral ring. The tumor soon occasioned marked disturbance. It was of doughy consistency, and cough failed to impart succussion. Percussson did not elicit a tympanitic note, and taxis failed to reduce it. As there was a doubt of its real nature, anæsthesia was produced with ether, and still taxis failed. The existence of symptoms of strangulation, viz: constipation, nausea, and vomiting, determined operative procedure, when an entero-epiplocele was disclosed. The omental element was the greater, and enclosed a small knuckle of gangrenous intestine; this constituent of the tumor was so small that the ordinary symptoms of succussion and tympany were rendered nondetectable. Hot water failed to develop manifestations of vitality, so the section of intestine was excised and the healthy ends stitched together. Suppression of urine followed the operation, and death resulted on the third day.

"Case 2 was an instance of inguinal hernia in a female advanced in years. Efforts at reduction by a number of physicians had failed. Notwithstanding the length of time intervening, I, however, by properly applying taxis, succeeded in reducing the tumor. The probable cause of failure on the part of other attendants was improper attempts at taxis. The mass pressed out over the ring in a manner to defeat their object. This is, in a majority of instances, the undoubted cause of failure in efforts at reduction.

"Case 3. A male, with complete right inguinal hernia—strangulated. Taxis failing, an operation was resorted to, but the case terminated fatally. The peculiarity consisted in a deposit of fibrin or lymph nearly two inches in thickness, surrounding the external ring.

"Case 4. A gentleman, whose vocation required at times heavy lifting, complained of a peculiar burning or stinging pain, limited to the right inguinal region, There was no perceptible tumor. The symptoms were invariably aggravated by physical effort. I diagnosticated incipient inguinal hernia, and advised a truss. The patient being dissatisfied, consulted an irregular physician, who ridiculed the diagnosis given, and administered homeopathic powders for nearly four weeks, with, of course, no result. By this time the hernia was protruded and unmistakable. The patient now wears a proper truss, and is practically well.

"In reference to umbilical hernia, I wish to call attention to the fact that the umbilical opening is comparable to the cranial fontanelles, in that, like the latter, it gradually closes with advancing age. Basing my plan of treatment on this physiological fact, I support the abdominal walls with a broad adhesive strip so applied as to approximate the umbilical region. To the umbilicus I adjust a compress *smaller* than the opening. This prevents protrusion without interfering with the closing process."

Dr. I. G. Heilman narrated the history of an aged colored man who suffered from an inguinal hernia which became strangulated. Anæsthesia with chloroform did not render reduction practicable. Drs. E. R. Stowe and L. B. Hall were called in, and, at the suggestion of the former, about a fluid ounce of a straw-colored fluid was evacuated from the sac by means of an ordinary hypodermatic needle. After this procedure, the hernia was easily reduced, and a favorable result followed.

Dr. L. Brewer Hall directed attention to the high prices asked by instrument makers for trusses, and inquired if there was any way by which the poor could get them at more reasonable rates.

Dr. Walker, in reply to Dr. Hall, explained how a ten-dollar truss could be obtained from a Chestnut street dealer, under such circumstances, for seven dollars.

Dr. Roberts, in closing the discussion, said: "In my opinion, the mortality in cases of hernia is due to two causes—first, too great an effort at taxis, whereby inflammatory changes are occasioned, and surgical treatment complicated and endangered; second, delay. If *gentle* taxis fails, herniotomy should promptly be performed. The conditions of delay and experimental manipulation by students at hospitals render hospital statistics of little value.

In one case of double hernia—*i. e.*, an inguinal and femoral hernia on the *same side*, I succeeded in maintaining them in place by an inguinal truss

so depressed as to occlude both the external abdominal ring and the femoral ring. In umbilical hernia, I apply a compress moulded of wax instead of the coin. It is more readily adapted to the size of the orifice, and kept in close apposition."

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

(*Concluded from page* 174.)

Case 3. Died in the Philadelphia Hospital, and the notes upon the case have been furnished me by Dr. Mary Farnham, resident physician.

A. J., æt. 50, nurse, weight, 150. Medium height, well nourished. Habits at times intemperate. For three weeks suffered from slight bronchitis though quite able to attend to work. October 24. 3 a. m. patient had a severe chill, accompanied by intense pain in the chest, left side, back, and limbs. Chill lasted an hour. At 8 a. m. was bathed in perspiration, surface livid, breathing difficult and painful: dullness on both sides, fine moist rales heard over both lungs. No valvular heart disease, but heart beat feeble. Œdema increased from hour to hour; at 2 p. m. free pinky serous exudation began to ooze from the mouth; at 4 p. m. lost consciousness; and at 6 p. m. died, cyanosed. On autopsy the only lesion discovered was intense congestion of the lungs.

In both these cases the history of previous alcoholic indulgence was supposed to be predisposing cause of the vaso-motor lesion, although the patients did not enter the hospital as subjects of alcoholism.

Case 4. Occurred in the practice of Dr. Whelen. The patient was a respectable married woman, who had been confined within two months of date of these symptoms. She was supposed to be in good health, and attended to her domestic duties as usual on the day of her death. At 10:30 Dr. W. was called to see her, and found her livid, with intense orthopnœa, unable to lie down, and a physical examination showed extreme pulmonary congestion of both lungs, with numerous rales. The patient expired at 12:30, within three hours of having been taken ill. Autopsy revealed only the signs of pulmonary congestion, without a hint as to a primary cause. I incline to think that in this case the neurility of the vaso-motor system had been reduced by lactation.

I pause at this point to observe that it is important to connect with the vaso-motor system instances of pulmonary congestion occurring in elderly persons with feeble hearts, but without sufficiently serious valvular disease, or degeneration of the heart to quite account for the symptoms. The treatment in these latter cases should be rather a general treatment by hygiene and tonics, than by directly treating the heart, which may be only secondarily responsible.

Digitalis is not so useful as a cardiac stimulant, possibly because it affects the heart too positively before the vaso-motor system is sufficiently acted upon. Indeed, the vaso-motor effect of digitalis may be absent when the action upon the cardiac muscle is decided. I allude to my observation of this clinical fact, because I am aware that recently it has been asserted that digitalis possesses a predominant action upon the vaso-motor system. I desire, however, to recur again to this subject.

Naturally, the vaso-motor derangement in Graves' disease suggests itself in this connection. The disease, as is well known, is characterized by the association of symptoms connected with the heart, thyroid gland, and eyeball.

The clinical fact which I desire to recall at this point is that the phenomena of Graves' disease illustrate the extreme susceptibility of the vaso-motor system to exciting causes, since the typical features of the disease are markedly increased at the menstrual period or during sudden emotional excitement.

In the Philadelphia Hospital, in the opposite bed to that occupied by the patient of Dr. Curtin's already mentioned, was a case of Graves' disease almost convalescent. The subject was so much excited by the unlooked-for death of his fellow patient that almost immediately the entire series of symptoms of thyroid enlargement, exophthalmos, and cardiac palpitation, reappeared.

Finally, in the recital of these cases which form the basis of this paper, the object in view is to call attention to the importance of recognizing the vaso-motor agencies operative in disease, and to indicate a plausible explanation of certain cases of anasarca. And in addition to present certain cases of pulmonary congestion due to vaso-motor weakness in the absence of the usual causes of the same.

Treatment.—In the treatment of vaso-motor dropsy it must be remembered that absorption of fluid from the tissues, like its exudation into them, is probably greatly controlled by the central nervous system. Dr. Brunton cites the experiments of Goltze and Nasse, in which the former found that when fluid was injected under the skin of the back of a frog it was rapidly absorbed, so long as the brain and spinal-cord were uninjured, but when these were destroyed little or no absorption took place.

Physiologically, absorption is under the influence of nerve-centres; therefore stimulation of these centres will increase their physiological functions. Stimulation of a sensory nerve is capable of inducing contraction of the entire vaso-motor system, and Nasse has proved that similar irritation will increase absorption.

Strychnia, digitalis, ergot, iron, and zinc, are capable of special impression upon the vaso-motor system, and these drugs are the chief agents with which to combat vaso motor forms of dropsy. Special diuretics may be used as adjuvants in grave cases, but never to the exclusion of the former.

In cases of vaso-motor paresis associated with cardiac palpitation, and other phenomena similar to those seen in Graves' disease, the use of the bromides should be condemned. When vaso-motor dropsy is extensive, agents which stimulate the functions of the skin may also be employed, and cardiac stimulants may be indispensable.

In the vaso-motor paresis associated with more or less pulmonary congestion and œdema, signal benefit has resulted from the liberal use of strychnia and atropia, by the mouth or by hypodermic injection; strychnia by its action as a respiratory stimulant aids in thoroughly oxygenating the blood, and thus promotes the efficiency of the circulation.

But it also acts not only on the dominant vaso-motor centre, but also on the vaso-motor centres distributed through the cord. These centres, to quote Lauder Brunton's words, are so feebly developed as not to heed ordinary stimulation, but can be aroused by the use of strychnia to lend their aid to increase the vascular tonus. This truth has also been proven by experiment; for after section of the spinal cord, which of course paralyzes the vaso-motor centres, the blood pressure can be made to rise by irritation of a sensory nerve.

The combination of atropia with strychnia unites the action of two powerful remedies in urgent cases, and together with cupping, these measures anticipate the slower action of digitalis.

Lastly, I desire to take this opportunity to observe that in cases of pulmonary congestion with degeneration of the heart, and vaso-motor weakness, with or without valvular disease, the association of strychnia with some pure cardiac stimulant, such as alcohol, is frequently superior to digitalis because this latter drug seems at times to produce an unfavorable effect. This unfavorable effect, well established clinically, is difficult to explain, except that the stimulant action upon the heart and pneumogastrics, slowing and steadying the heart, is not associated with corresponding vaso-motor stimulation, and the pulmonary repletion persists. Again, in valvular heart disease the lesion may be so great that two powerful systoles tend to increase pulmonary congestion by forcing the blood in two directions. Thus, the expression that digitalis depresses the heart is sometimes used, and practically such patients are better off without this drug.

Periscope.

A Case of Bilateral Herpes Zoster.

The occurrence of this disease attacking both sides at the same time is sufficiently rare to warrant the reproduction of the case which Dr. J. Magie Finny reports in the *Brit. Med. Jour.*, January 10, 1885 :

Mrs, D., aged 40, an otherwise healthy well-to-do woman, consulted me on September 29, 1884, for what she feared was erysipelas of the neck and ear, and for a most severe headache, which had lasted for four days and had deprived her of sleep. She stated that the headache was all over her head, but particularly on the right side, and that at the time of its first appearance she noticed a number of small red spots on the left side of her neck and shoulder ; that these spots had a burning, "sore" pain, that they had increased in size and number since the day before her visit, and that also her right ear was very sore, while a number of painful spots had broken out through her hair on the back of the scalp on the right side.

On inspection the characteristic erythematous patches of herpes zoster, studded with vesicles of various sizes, were at once recognized; and it was evident that both sides were simultaneously affected, although at a somewhat different level. On the left side, the erythematous patches were most numerous ; they followed the distribution of the descending sensory nerves of the cervical plexus, with the exception of the supra-sternal division, and were limited to the upper part of the deltoid and pectoral muscles; a large patch occupied the posterior superior triangle of the neck, and one or two small ones were over the sterno-mastoid. The eruption on this side would correspond to von Bärensprung's variety, *Z. cervico-subclavicularis*. On the right side, the ascending branches of the second and third cervical nerves were those engaged (*Nervus occipito-collaris*), and no patches were visible below the level of the thyroid body, though a large cluster occupied the anterior triangle of the neck as far forwards as that body, corresponding to the junction and cutaneous distribution of the superficialis colli and infra-maxillary branch of the facial nerve. Another patch was on the lower jaw, and a third was situated near the mastoid, over the origin of the plexus. The whole of the external ear was read and swollen, and thickly studded with very minute vesicles, the swelling extending a short way into the meatus auditorius. The scalp on the same side, and strictly limited to that side, as far forward as the mid-parietal region, was the seat of a number of scattered pimples and vesicles (the redness usual in herpes elsewhere being absent), and which followed closely the course of the greater and lesser occipital nerves.

When the patient was seen a few days subsequently, the majority of the bullæ had been arrested or had aborted, some few had become confluent and turbid, and those in the scalp were larger, and most distinctly bullous. The patient's general health had been fairly restored, as she was able to sleep, and the headache and the burning stinging pain in the affected parts had greatly abated. No new spots had appeared, but on the right side, above the clavicle, where the skin was free from all rash, very considerable soreness was complained of.

The treatment consisted of quinine and iron, in combination with sulphate of magnesia, and the local application of flexible collodion to the neck, and weak carbolic ointment to the scalp. The patient soon recovered.

Remarks.—The foregoing illustrates at once the characteristic features of regular herpes zoster and certain unusual peculiarities. To the first belong (*a*) the sudden occurrence of the eruption, (*b*) its course along the cutaneous distribution of the sensory nerves, (*c*) the neuralgic phenomena which preceded and accompanied its appearance, and (*d*) the acute course of the complaint. To the latter may be referred (1) the occurrence of herpes of the scalp, and (2) the co-existence of the disease ta different sides of the neck.

Herpes zoster, or as I consider it might be termed with a nearer approach to an accurate nomenclature, *neurotic herpes*, may be found in almost any part of the body. It has, however, its predilections for certain parts, if one may be permitted so to speak of a disease. The most favorite sites are in the course of the intercostal nerves and the lumbo-sacral plexus; next in order come the brachial plexus, the descending branches of the cervical, and the frontal or facial branches of the fifth nerve. Among the most rare, are the occipital nerve and the nerves of the forearms and legs.

The chief interest of the foregoing case is, however, centred in the fact that the herpes attacked both sides at the same time. This is one of the rarest manifestations of a not uncommon affection; and, indeed, in many of the most recent text books, the possibility of zoster being bilateral instead of only on one side, is not even mentioned. "Unilateral herpes" is the name by which it is sometimes known; and the recognition of the almost invariable rule of its attacking but one side of the trunk, extremities, or face, is of great diagnostic value in contrasting it with catarrhal or simple herpes, which attacks one or both sides indifferently. In the comparatively few instances on record of bilateral herpes zoster, the eruption, as in the above case, is not on exactly the same level; but the cutaneous nerves attacked on one side are on a higher or lower level than those on the other side.

Resection of the Large Intestine for Scirrhous Growth.

Mr. Sidney Jones reports the following case in the *Lancet*, January 10, 1885:

W. K——, aged fifty-four, married, was admitted under the care of Mr. Sydney Jones on May 15, 1884, and died on the 26th.

The family history was good, and there was no record of tumor. She married twenty-nine years ago, and had had seven children, the youngest of whom is aged sixteen. Four died from measles or scarlet fever; the others are living and healthy. She had had no miscarriages. She has suffered from herniæ since the birth of her first child (right inguinal and femoral); for these she had worn a truss, but only for two months. Six months ago she felt pain in the right side of the abdomen; this pain was worse during and after exercise, and she knew of no cause for it. Four months ago she noticed a swelling in the part of the abdomen where she felt pain; it increased in size, but has not changed in position. The pain has been worse after a hearty meal and during exercise, but she did not think that she had lost flesh, and her appetite continued good. She had always suffered from constipation, but since Christmas the bowels had been more than ever confined, and her motions had been of a dark, almost black color recently, but she did not know that she had ever passed blood. The catamenia ceased about seven years ago; until then, she was quite regular.

On admission, she was a thin, pale woman, with an anxious expression, complaining of a swelling in the abdomen. On the right side of the abdomen, about the level of the anterior superior spine, was a solid tumor, about two inches and a half in diameter, of very irregular outline. It appeared to be attached to the abdominal wall, did not move with respiration, but was not fixed; it could be moved from side to side. It was tender to the touch, firm and hard, and somewhat irregular on the surface. The resonance of the abdomen generally was good, but was modified over the tumor; there was not absolute dullness. The abdominal walls were lax, and there was a hernia in both the inguinal and femoral regions on the right side, the former easily descending when the patient stood, and being easily reduced with gurgling; the latter small, descending less easily. The organs generally were healthy. Urine, 1027; no albumen; contained a little mucus. The patient suffered a great deal of pain, and was anxious for something to be done to relieve her.

May 23. The patient having been prepared for the operation in the usual manner, and the bowel cleared by an enema, she was put under the influence of ether, and Mr. Sydney Jones performed the following operation: An incision four or five inches in length was made from above downwards over the centre of the tumor, and when the abdominal walls had been divided and bleeding points ligatured, the carbolic spray was turned on, and the remainder of the operation was completed under it. The tumor was found flattened and adherent to the peritoneum, and there was slight bleeding when it was separated; it was found tg be situated in the upper part of the ascendino and part of the transverse colon. A warm sponge was placed over the exposed intestines whilst the diseased portion was examined. It was decided to excise the cæcum and all that part of the intestine which was involved. The mesentery and omentum were ligatured by silk ligatures, piece by piece, and then divided. A clamp covered with India rubber was put on the intestine on each side of the line of proposed separation, and the intestine was then divided by scissors, and any bleeding points twisted with forceps. A small piece of sponge was inserted into the open end of the ileum whilst the tumor was being dissected out. The tumor and involved intestine were removed from the transverse colon in a similar manner. It was decided to bring the two ends together without making an artificial anus. About fourteen fine silk sutures were passed through the whole thickness of the intestine, so that the two cut ends were united around their whole circumference; others were passed through the serous coat alone, and one was passed (near the wound), so as to attach the serous coat to the abdominal wall. After the clamps had been removed, there was a little ecchymosis and congestion of the gut near the place where they had been applied. The abdominal cavity was then carefully wiped out with dry warm sponges, and three sutures were passed through the upper part of the edges of the wound and one through the lower; the middle part of the wound was left open, and a light plug of iodoform gauze was inserted into it. The wound was dressed antiseptically, a bag of sublimated wood-wool being used to soak up any discharge, and this was bandaged on with carbolic gauze bandages. The pulse was good after the operation. A half-grain supposi-

tory of morphia was given before the patient was put back to bed.

24th. She complained of pain occasionally during the night, and did not sleep for more than half an hour at a time, although injections of morphia were administered at seven and eleven last evening. The urine was drawn off every eight hours. Temperature last night 98.4°; this morning 100°. She had another injection of morphia in the early morning, and suffered no pain during the early part of the day. Pulse 134, bounding and easily compressible; respiration easy (25); tongue dry; has taken ice only; urine 1030, acid, a deposit of lithates, no albumen, some mucus. 2. p. m., temperature 101.2°, patient quiet and without pain. 8 p. m., temperature 104.4°, restlessness, no pain. The wound was dressed on account of the rise of temperature; the plug was found covered with quite sweet coagulum; the dressing gave no pain; the spray was used. The wound looked well and there was no abdominal distention. An injection of one-third of a grain of morphia was given, after which she slept for two hours.

25th. The patient seemed better, no pain; pulse 124 at noon, and occasionally intermittent; temperature, 2 a. m., 103.8°, 8 a. m., 103.6°, 2 p. m., 103°, 8 p. m., 102.6°.

26th. She slept about two hours during the night after the injection of one-third of a grain of morphia. She became weaker towards the morning, and her temperature rose to 104.4° at 2 a. m. She was worse at 8 a. m., when the temperature was 104°, and a teaspoonful of brandy was ordered to be given every hour. 11 a. m., she was sinking; the pulse could hardly be felt, temperature 104.4°. An injection of ether and a nutrient enema were given, after which she revived a little, but sank, dying quietly at 1:45 p. m.

At the post-mortem examination, made on the following day by Dr. Sharkey, the abdominal cavity contained no fluid, and there was no general peritonitis. The site of the operation was the right iliac and lumbar region, where the small intestine had evidently been united to the large after a portion of the bowel had been removed. The line of junction was very vascular, but there was no inflammation except at the point where the mesentery was attached; here dirty-looking pus had infiltrated the tissues. Water injected through the gut passed freely and easily by the seat of the operation; but on putting a little more pressure a larger, but still moderate, stream of water trickled through the wall of the gut at the junction of the mesentery with it. This slight oozing was probably the cause of the local inflammation. There was a moderate degree of atheroma of the valves on the left side of the heart; the lungs were both greatly congested and œdematous in dependent parts; the kidneys were rather small, and their capsules very slightly adherent; otherwise the organs were healthy.

Remarks.—Having little doubt as to the nature and seat of the growth, and taking into consideration the inevitable ending if no operation were performed, either from local extension and involvement of surrounding parts or possibly obstruction of the bowel from diminished calibre of the gut—the patient suffering much pain from the growth, which was increasing somewhat rapidly in size, and being anxious for relief—Mr. Sydney Jones performed the operation described above; and the general local condition (there being no enlargement of the neighboring glands nor visceral disease, as proved post-mortem) justified the expectation of a successful result.

Treatment of Vascular Hypertrophy of the Nose.

Dr. J. Herbert Stowers thus writes in the *Brit. Med. Jour.*, January 10, 1885:

Occasionally, allied to acne rosacea, we meet with instances more or less severe of hypertrophy of the nose. Apart from cutaneous disorder, cases occur in which simple passive congestion of the organ exists, attended with troublesome subjective symptoms, as tenderness, throbbing, irritability, etc.

I am not aware that any special treatment has been advocated for the above, neither do I know that in any published treatise vascular hypertrophy of the nose is fully dealt with.

Chronic passive congestion leads to connective tissue increase, and to the production of lasting deformity; indeed, examples of such must be familiar to all. I do not contend that cases of long standing can always be cured by the method I propose, especially when the apex is pendulous or bulbous, but in acute rosaceous acne, simple passive congestion with enlargement, or fibrocellular hypertrophy, I would commend with much favor the adoption of the plan described by the title "multiple punctiform scarification."

Hebra, years since, suggested that for the more effectual treatment of erythematous lupus, a bundle of scalpels should be tied together, to enable many more or less deep punctures to be made perpendicularly to the surface in the skin by one movement of the hand.

At the instigation of Dr. Sangster, physician to the skin-department of the Charing Cross Hospital, a convenient instrument has been devised whereby the necessary number of minute double-edged steel blades can be included in one handle. Such an instrument I am enabled to show you at this time.

The intense congestion of the skin in rosaceous acne I had often permanently relieved by local depletion, but it was not until I was familiar with this instrument that I learnt the lasting benefit resulting from frequent blood-letting in this and more aggravated states. After the congested organ has been thoroughly fomented with water, as hot as it can be borne, for several minutes, it should be held, and somewhat compressed, between the left thumb and finger of the operator, and then rapidly punctured with the instrument, (two or more blades of which are "guarded" to prevent too deep insertion), perpendicularly to the surface, from base to apex. The compression considerably reduces the pain attendant upon the procedure.

It must necessarily be at the discretion of the practitioner in what cases, and how often, this plan should be adopted and repeated.

Although the number of punctures must vary with the severity of the case, the narration of three cases under my care, permanently benefited, will, I hope, be useful and instructive. These were respectively under treatment seven months,

seven months, and five months, and the corresponding number of punctures in each case were 15,750, 11,150, and 52,200. The average number of punctures tolerated at one sitting will, of course, also vary with the sensitiveness of the part and the endurance of the patient. I have found by experience that from 500 to 3,000 is about the average, for, necessarily, the process is followed by temporary inflammatory swelling, which, however, soon subsides.

The average interval I have allowed to elapse between each operation, has varied from five days to a fortnight, and the quantity of blood abstracted from one to three drachms.

Smearing the surface with vaseline, and protecting from the outer air, especially in cold weather, is the only additional treatment needed, besides such internal remedies, saline aperients, alteratives, etc., as the general condition of the patient may indicate. I may add, I have seen no complication, or untoward symptom, result from this method. The use of alcohol must be emphatically denied.

I repeat, in all instances, lasting and satisfactory results have been procured, and are attributable to the local depletion, which allows recovery of tone of vessels, the contractibility of which has not been permanently destroyed, and also to the invisible scarring which, by after-contraction, reduces the vascularity of the skin. This after-scarring is hardly discernible.

I regard this method as capable of preventing cellular, and fibro-cellular, hypertrophy, which results from long-continued passive vascular congestion of the nose.

Case 1. Elizabeth W., aged 42, single. Duration, five years. She had frequently taken spirits for alleged "weak heart." Debility, dyspepsia, and dysmenorrhœa. Total, 15,750 punctures, distributed over fifteen sittings, and a period of seven months. Commenced January, 1883. Result permanent and satisfactory.

Case 2. A surgeon, suffering from acne rosacea and vascular hypertrophy. Duration, eighteen years; commencing at the age of fifteen. He had suffered from atonic dyspepsia. In twelve separate sittings, extending over a period of seven months, 11,150 punctures; commenced January, 1882. Result permanent and satisfactory.

Case 3. Patrick P., aged 50. Plethoric; health good. Duration, six years. Very abstemious. Total, 52,200 punctures, included in twenty-two separate operations, over a period of five months. Commenced December, 1882. Result to present, permanent and satisfactory.

A Cherry-Pit in the Ear of a Child.

Dr. David Webster reports this case in the *Archives of Pediatrics* for November 15, 1884:

On Thursday, July 24, 1884, at 11 a. m., a girl, nine years of age, while engaged in a frolic, had a cherry-pit blown into her right ear from the mouth of an older sister, with whom she was playing. Half an hour later, she appeared at the office of the family physician, who happened to be absent. She was then taken to the office of another doctor in the same village, who tried to remove the foreign body with a hair-pin, and failed. At one o'clock the same day she was taken again to the family physician, who tried to remove the pit with a small dissecting forceps. The tenderness by that time was very great, and the child had become so intolerant of manipulation that his effort was very short. He therefore sent the child away, advising delay. Nothing more was done to the ear until Sunday, August 3, when the doctor went to the house and tried syringing for half an hour. Not succeeding, he put the child under ether, and tried again to remove the pit with forceps; but as he found he could not readily grasp it, he "gave it up," and on the following day, August 4, he brought the child to me.

Upon examination, I found the auditory canal red, swollen, and sensitive at its inner third. The swelling seemed to diminish the lumen of the canal by about one-half. The extremity of the canal was blocked up by a reddish mass, which was hard to the touch of the probe, and insensitive. From the history, I had no doubt that this was the cherry-pit. The hearing power of the ear was reduced to 2-60, as measured by my watch. The child had suffered pain only during, and immediately subsequent to, attempts to remove the foreign body.

The question now arose as to what would be the best course to pursue. It was evident that it would be extremely difficult to remove a hard, unyielding body like a cherry-pit through a passage having a diameter much smaller than its own. Any effectual attempt to do so would necessarily involve a very considerable amount of violence to the parts. Therefore, as the symptoms were not urgent, I thought it would be wiser to delay any operative interference until the swelling of the walls of the canal had subsided. I advised that the ear be douched with warm water thrice daily by means of the fountain syringe for a week, when the child should be brought to me again, and then, if the conditions were favorable, I would attempt the removal of the foreign body. About a week later, instead of seeing the patient again, I was gratified by receiving a letter from her family physician, in which he stated that on Friday, August 8, after having douched the ear thrice daily, as advised, for three days, the cherry-pit came out while the douche was being used.

It is probable that in this case the foreign body might easily have been removed in the first place by a judicious use of the syringe. It is not improbable that every attempt at its removal by means of the hair-pin and the forceps, only lodged it deeper in the canal, and irritated the contiguous parts, thus helping to increase the swelling of the walls of the passage, already inclined to resent the presence of a foreign body.

I have not seen the patient since, but her physicician, to whose kindness I am indebted for so complete a history of the case, informs me that the hearing is still considerably impaired.

The Etiology of Catarrh.

Dr. George F. Burder thus conclues an article in the *Bristol Medico-Chirurgical Journal* for December, 1884:

The positive conclusions at which I arrive are the following:

1. Catarrh is promoted by the cold of winter, and is greatly checked by the heat of summer.

2. It is promoted by one or more of three causes which occur together—namely, deficient rainfall, dryness of air, and northeasterly wind.

But I need hardly point out how unphilosophical it would be to infer from these results that either the cold, or the dryness, or the northeasterly wind is the essential cause of catarrh. Plague, cholera, and yellow fever are all in a marked degree under the influence of atmospheric conditions, notably of temperature; yet no one believes that either of these diseases is the direct product of heat, or hesitates to assign it a place amongst the zymotic group.

I apply the same principles to catarrh. I believe it to have its origin in a specific organism, the germs of which float in the air. This organism, like other organisms, is dependent for its activity and propagation upon atmospheric conditions. Unlike many, it thrives in cold and languishes in heat. Dry northeasterly winds bring to it life and vigor; while southwesterly winds depress its energies, and the rains which accompany them wash it away. Drawn into the air-passages with the breath, it lodges in the mucous membrane, where, probably, it multiplies and spreads, giving rise to the local symptoms of a cold. There may be nothing more than this, or the organism, penetrating the tissues, may find its way into the blood, and, by its presence in the circulating fluid (where again it multiplies), may set up a state of fever.

To conclude, if the subject of my discourse seem comparatively trivial, I may be allowed to plead that in science nothing is trivial; and that as no error can fail to be hurtful, so no truth can fail to be helpful, and that in a degree not to be measured by the intrinsic importance of the subject to which the truth or the error immediately refers.

Concussion of the Spine and its Relation to Neurasthenia and Hysteria.

Dr. C. L. Dana publishes a paper on this subject in the *New Orleans Med. and Surg. Jour.*, January, 1885, which has for its object the demonstration of the following points:

1. That the term spinal concussion is a misleading and often incorrect one, and that the symptoms which are usually associated with that name are really symptoms of traumatic neurasthenia, hysteria, and hypochondriasis, associated, more or less, with symptoms of injury to the vertebral ligaments and muscles, and to the spinal nerves; that, in other words, spinal concussion is mental shock and physical bruising.

2. That this traumatic neurasthesia is in a measure a real disease, though it is very hard to say how much is real and how much the patient puts on.

3. That it may be, and often is, simulated, and that it requires the greatest care to detect skilled imposters.

4. That we need more objective tests for the purpose of determining the existence of these subjective neuroses.

5. That the prognosis of railway or traumatic neurasthesia and hysteria is very good so far as steady improvement is concerned, not so good as regards complete recovery.

6. That concussion of the spinal *cord* alone, followed by temporary loss of function, or by myelitis, does occur in rare instances.

7. That, in the predisposed at least, injuries and jars may set up chronic myelitis, without there being a lesion of the spinal column.

8. That Mr. Erichsen has, in his book on "Spinal Concussion," erroneously attributed functional troubles to the result of organic spinal disease.

9. That Mr. Erichsen's book on "Spinal Concussion" has a strong tendency erroneously to attribute to a shaking of the spine and a supposed ensuing meningitis, symptoms really due to mental shock, peripheral injury, or malingering.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Those interested in the cure of idiotic and feeble-minded children will read with pleasure a paper on the proper provision for them, by Dr. Isaac N. Kerlin (Boston, Geo. H. Ellis). The author is superintendent of the institution for such cases at Media, Pa., and speaks from a broad and carefully-studied experience. His views may be accepted as those most thoroughly representative of the latest studies in this specialty.

——In a reprint before us, Dr. E. C. Morgan, of Washington, D. C., cites some interesting cases of aphonia due to chronic alcoholism.

——A useful article on the varieties of the induction coil, and the indications for its use, by Dr. A. D. Rockwell, of New York city, has been published in separate form.

——The "Report on the Prevention of Cholera," By Dr. J. H. Raymond, of Brooklyn, looks toward energetic sanitation as the true means. He quotes with approval the words of Sanitary Inspector Chadwick: "The proved secret of cholera prevention is cleansing, keeping clean, pure water, drainage, looking after all epidemic localities, and getting the people out of them. We found in old times that not many yards separated deadly spots from safe ones. For treatment, house to house visitors to look after premonitory diarrhœa, and one of the most essential provisions is some place for treating cases as closely as possible to the attacked house."

——*Godey's Lady's Book* continues to improve month by month, and is now one of the most agreeable family periodicals in the market.

BOOK NOTICES.

—

The Internatianal Encyclopædia of Surgery. Edited by John Ashhurst, jr., M. D. Vol. v., 8vo., cloth, pp. 1207. William Wood & Co., New York.

The present issue of this large work is occupied with the surgery of the head and its parts, of the neck, chest, breasts, and abdomen, including hernia. The contributors are fourteen in number. Dr. C. B. Nancrede writes on injuries of the head; Mr. F. Treves on malformations and diseases of the head; Dr. E. Williams on diseases and injuries of the eye; Dr. A. H. Buck on diseases and injuries of the ear; Dr. Geo. M. Lefferts on the nose and sinuses; Dr. A. C. Post on the surgery of the face, cheeks, and lips; Mr. Christopher Heath on the mouth, fauces, tongue, palate, and jaws; Dr. N. W. Kingsley on the teeth and adjacent parts; Dr. Geo. H. B. Macleod on the surgery of the neck; Dr. J. Solis-Cohen on the air-passages; Dr. E. H. Bennett on injuries of the chest; Mr. T. Annandale on injuries ot the breast; Mr. Henry Morris on the abdomen; and Mr. John Wood, of King's College, London, on hernia.

It will be seen that there is a goodly array of names here, and the character of the work is sufficiently guaranteed by mentioning them. The publishers have done their part well, furnishing numerous illustrations, chromo-lithographic and on wood, and presenting the text well printed on good paper.

Organic Materia Medica. A Manual for Students, Physicians, and Pharmacists. By John M. Maisch, Phar. D., Professor Materia Medica and Botany in the Philadelphia College of Pharmacy. *Second Edition.* Lea Bros. & Co., 1885.

This work has been eagerly looked for for over a year, the first edition having been exhausted that long ago. It fills a place that no other book we know of is able to fill as well. True, our dispensatories contain it all, but no student preparing for his examinations has time to cull from them what he must know. A large part of their contents is matter that, of course, it is advantageous to read over carefully, or that is merely for purposes of reference. But this work contains the substance—the *practical* "kernel of the nut" picked out, so that the student has no superfluous labor in searching through the larger works. Besides, not having time to do it properly, he is not always, if ever, competent to decide what is of greatest importance to him, what will be of practical value, and, in short, what he should and must know; but he can confidently accept what this work places before him, without any fear that the gist of the matter is not in it.

Another merit is, that the drugs are placed before him in such a manner as to very much simplify the study of them, enabling the mind to grasp them more readily. The illustrations, which number 242, are most excellent, being very true to nature, and are alone worth the price of the book to the student. It embraces the drugs of the United States and British Pharmacopœias. To the practical physician and pharmacist, it is a valuable work for handy reference, and for keeping fresh in the memory the knowledge of materia medica and botany already acquired. We can and do heartily recommend it. Though a book of over 500 pages, yet it is of a very convenient size to carry or study. The typography, paper, and binding are up to the usual high standard of the publishers.

A Manual of the Practice of Surgery. By Thomas Bryant, F. R. C. S., etc. With 727 illustrations. Fourth edition, thoroughly revised. 1 vol., large 8vo., pp. 1039. Philadelphia, Henry C. Lea's Son & Co., 1885.

Evldently Mr. Bryant has satisfied the expectations of a great many surgical readers, with the rapidity with which edition follows edition of the work before us. Each issue receives his close attention before it sees the light, and is a positive improvement on its predecessor. He is a very just writer, and acknowledges without ambiguity the discoveries and inventions of other surgeons, while he does not yield too easily to the temptation of novelty.

While the volume is a large one—too large to be termed with propriety a "manual"—it is, we are convinced, a decided advantage to the reader, to have the whole conspectus of the science in one, rather than in two or more volumes. The tendency of late years has been for all authors to run into works of encyclopedic dimensions, much to the discouragement of students and readers.

The treatise takes in the whole field of surgery, that of the eye, the ear, the female organs, orthopedics, venereal diseases, and military surgery, as well as more common and general topics. All of these are treated with clearness, and with sufficient fullness to suit all practical purposes. The illustrations are numerous and well printed, and the manufacture of the work is in all respects satisfactory. We do not doubt that this new edition will continue to maintain the popularity of this standard work.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address
DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

AGAIN A SALE OF AMERICAN DIPLOMAS IN EUROPE.

The following editorial article appears in the edition of the *Deutsche Medizinal Zeitung* (one of the best, if at present not the best German medical journal) of December 22, 1884. As it can only be of advantage to the medical and dental profession of our country to make the swindle as widely known as possible, and to denounce it in public journals, we bring in the following a verbatim translation of the article in question, whereby we cannot conceal that affairs of this kind by no means contribute to our reputation in Europe.

"*Swindle — Doctor — Diplomas.* The *German Monthly Journal for Dentistry*, 1884, publishes the following interesting communication of Dr. Adolph Petermann, in Frankfort-on-Main:

The *Frankfort Daily* brought in its advertising columns the following announcement:

"Doctor-diplomas of Dentistry, Philosophy, Jurisprudence, etc., are reliably and discreetly procured. Address, C. R. (care of Stationer), 10 Duke street, Bloomsbury, London, W. C."

An inquiry under a fictitious name was responded to from London by two letters from a "Professor" G. Rummler. The first letter is not worth publishing, containing but a general offer and assuring discretion. The second letter was as follows:

LONDON, 32 THORNHILL CRESCENT,
BARNSBURY, March 10, 1884.

Dear Sir: In answer to your favor, I respectfully inform you that you have to deal with an honest man, who will procure you the diploma only from a reliable institute, legally authorized to issue diplomas. The name of the institute is: "Wisconsin Dental Academy."

You may deposit the fee with any banking firm in Frankfort, and have the deposit certified to by the firm and communicated to me, whereupon I shall at once order the diploma for you. If you do not wish to confide in a banking house of your city, it will be best if you will send to me 200 marks (about $70) at once, and the remaining $70 on receipt of the diploma. Any other expenses besides the $140 you have not. Please inform me, when ordering the document, of all your Christian names.

Further, I beg you to sign the enclosed printed

application for graduation at the place where you read the word, "signed." All the rest I shall fill out. You will see at the back of the blank the attest of the President of the Academy that the degree is only conferred, if recommended *by me.* It will take about five weeks ere I can deliver the diploma to you.

Awaiting your reply and the return of the application signed, I am, etc., etc.,

PROF. DR. G. RUMMLER.

The words on the back were *written* as follows:

"DELAVAN, WIS., U. S. A.

"This statement will be honored from any practicing dentist if endorsed by Prof. Dr. Rummler. GEO. MORRISON, *President.*"

The "honest man," "Professor Dr." Rummler, therefore, procures anybody (also under a fictitious name), without trouble, for a payment of $140, and *without any scientific attainments or examination*, a doctor-diploma from a chartered Wisconsin Dental College! Nice state of affairs!

From a former article of mine on the same subject, it will be seen that Mr. Morrison delivers even for $12 such a diploma, while here $140 are demanded. Indeed, Mr. Rummler is engaged in a dirty, but profitable business.

Amongst the advertisements of the *Kladderadatsch* is the following:

"Doctor Diplomas of Dentistry. Their legality officially attested. Discrete and reliable. B. Walden, 41 Princes Square, Kensington Park, London, S. E."

On inquiry at the above address, one receives the reply from Berlin from Dr. Olschowsky, 100 Linden street. Mr. O. is gladly willing to procure the doctor-diploma from an American university, respectively a dental college, whose sole representative he is. After he has mentioned that the institute is legally entitled to confer "honorary doctor titles," he continues, verbatim, as follows: "You are permitted, therefore, to call yourself a doctor here, if you only add to it: 'Conferred in a foreign country,' or, 'not conferred here.' You may see in every Berlin newspaper, especially the *Tageblatt*, that they daily contain many advertisements of this kind, with these words added: "To procure you the diploma need for the beginning only a short curriculum of your life, and I shall then take care of the rest and send you the diploma all filled out, so that you need neither interrupt your daily occupation, nor do anything whatever."

Finally, O. informs the applicant that the whole expenses amount to $200, and that pre-payment is not needed, only the deposit of the sum with a reliable business firm, but best with W. Marzillier & Co., Berlin, S. W., 25 Mörkern str.

On further inquiry, Dr. Olschowsky answers, that all these things "must pass through his hands, as the college does never correspond directly with anybody else," and "that the college in question was situated in Delavan." In a third letter the application for promotion arrived, in a fourth Dr. O. advises quickly to conclude the affair, and in the fifth letter Dr. O. tries to quiet any fears of the questioner, in so far as he tells him that Prof. Morrison, the President of the Wisconsin Dental College, comprehends by practicing dentist only dental technic, and that dental surgeon meant something else. Dr. O. concludes verbatim. "It says, therefore, in the diplomas, which I shall obtain for you, not Doctor of Dentistry, but Doctor of Dental Surgery. Besides I have already procured this diploma for applicants, of whom the gentlemen across the ocean knew that they were not dentists, and it is therefore the same with you. I hope to have removed your scruples, and expect immediate conclusion of the affair, which opportunity I use to inform you that $100 will meanwhile suffice."

Dr. Olschowsky, who has already formerly been active in the distribution of Buchanan's (the so-called Philadelphia) diplomas, now endeavors, therefore, to sell the totally valueless honorary doctor-diploma of the *Wisconsin Dental College, in Delavan, Wisconsin, U. S. A.*, at the price of $200, while the same bogus diplomas are procured through Prof. Dr. Rummler, in London, for $140, and from the Wisconsin Dental College itself for $12. I have sent the letters of Dr. Olschowsky to the Imperial Secretary of the Interior (of Germany), and thus we may hope that from there this dirty trade may be suppressed.

This barter and sale of American diplomas in

Europe ought to be thoroughly exterminated at its source, *i. e.*, in our country; and it would be desirable that all legislatures, or Congress, should pass the most stringent laws, not only declaring the charter of such swindling institutions null and void, but also punishing with penitentiary at solitary confinement and hard labor, for a long period of years, any violation of the law. Of late years our profession has striven most earnestly and successfully to occupy the same rank with its European confréres. American dentistry is recognized all over the world as far ahead of that of other countries; but if American physicians and dentists permit the existence of such swindling institutions, and the sale of bogus diplomas to continue under their very noses, then they must not feel offended if they, on visiting Europe, are looked upon with suspicion, if no special credentials convince their professional brethren across the water that they (the American physicians and dentists) really are graduates of a respectable college.

It is scarcely possible that there can be many such diploma manufactories, and the few that still vegetate ought to be easily eradicated.

CONTAGION OF CHOLERA.

In a report which Dr. Monilleron made concerning the contagious character of Asiatic cholera to the French Academy of Medicine, and which was read by Dr. Proust at the December meeting of this society, the following two cases are mentioned:

1. The French steamer "City of Palermo" passes Gibraltar, and there replenishes its supply of fresh water; it arrives July 17 in Marseilles, stays there until the 24th, and consumes while in this port the water received in Gibraltar. On the 24th fresh water has once more to be taken on board, this time in Marseilles. Two days after leaving Marseilles five persons were attacked by cholerine, and on the 30th one of the ship's boys was seized with a well-pronounced case of genuine cholera. None of the sick died. Although the scientific proof has not been thus given, that the fresh water supplied in Marseilles on the 24th, and drank from that day by the crew, had given rise to the disease, all the surrounding circumstances are in favor of this view.

2. The steamer "Abdel Kader" leaves Marseilles September 18, and arrives on the 20th in Philippeville. While at sea a suspicious case of death occurred. In consequence of this incident, crew and passengers—together, 465 heads—are transported to the Lazaretto of Fort Génis, near Bône, where no case of the disease had yet been observed. Of the 465 individuals 59 then were seized by cholera (19.7 per cent.), and of these 59, nearly one-half, viz., 29 (49.1 per cent.), died. On account of the severity of the epidemic, all the passengers and the crew were separated in various groups, stationed about four miles apart from each other. At once the disease diminished, and soon ceased completely. Without a doubt, the malady originated with the first case of death on board of the ship, and was rapidly propagated in consequence of the accumulation of so many people in comparatively so small a space. It is to be supposed that amongst the many passengers, many evinced a special tendency toward the epidemic. In Bône, which is situated about five miles from Fort Génis, not a single case of the disease occurred, there having been no communication whatever between Bône and the affected district.

These instances prove the contagious character of cholera, its propagation by human beings, and the possibility of its prevention by complete isolation.

THE CONTAGION OF INSANITY.

A sad example recently occurred in New York city of a distinguished expert in insanity who himself fell a victim to that disease.

This revives a question which we have seen broached on several occasions, but which deserves more attention than it has received.

There can be no doubt but that under certain conditions mental maladies are contagious. An epidemic of hysteria is far from uncommon in the women's wards of hospitals. Epilepsy has been known to arise from witnessing a seizure. Certain forms of hallucination seem to sweep periodically over communities, attacking large numbers.

The dancing mania of the Middle Ages corresponded to the tumblers and twisters of the revival scenes in the Western States in 1803–5. The delusion of witchcraft which possessed the minds of the most godly and the most learned in the seventeenth century, finds its counterpart in the not less absurd delusion of spiritualism, which to-day numbers among its believers men high in place and in society.

Like other contagions, the liability to this one varies much with the person. We once asked the superintendent of a large asylum whether he recognized a tendency in sane persons who associated much with the insane gradually to develop delusions. He assented at once, but claimed that it was true only of a limited number, and these, he added, should at once be removed from all association with the mentally diseased.

A German traveler who reports his visit to Gheel, in Belgium, the celebrated "ville des fous," where thousands of idiotic and insane persons live, asserts that the mental powers of the native inhabitants have been distinctly lowered by this constant association with deranged intellects.

The practical lesson from all this is that he who proposes to devote himself to the study of insanity should be very certain that he has no neurosis, hereditary or acquired, which would be liable to be developed by the examples and associations he must necessarily fall in with in pursuing that specialty.

Notes and Comments.

Cerebral Syphilis.

This subject, about which we have already made some remarks, based principally upon the observations of Prof. H. C. Wood, is well illustrated in a case which Dr. James T. Whittaker reports in the *New England Medical Monthly* for January, 1885. It will be remembered that Dr. Wood called attention to the fact that cerebral syphilis is usually a very late manifesfation of the disease; that it oftentimes does not come on for fifteen, twenty, or even more years after the occurrence of the original lesion. In Dr. Whittaker's case the patient, a woman, had contracted syphilis from her husband twenty-four years ago. Being ignorant of the nature of her disease, she allowed the first and second stages to run their course, extending over a period of three years. As well illustrating the history of cerebral syphilis, we give the balance of this case in Dr. Whittaker's own words:

"Since that time she has had no illness, except an occasional enlargement of the glands about the head and neck, and a post-nasal catarrh, which at times gives her considerable annoyance. About fifteen months ago she began to notice a numbness about the lower limbs, which grew so severe that she could not walk, and in the arms and hand so that she became unable to hold anything in her grasp. She next became unable to talk well, both from an inability to seize the right word, and because of a sensation as if her tongue had become thickened. She often had to hesitate for the proper word, and at times her utterances were broken so as to be almost unintelligible. At the same time her sight became dim. After these symptoms had continued for about two weeks, they became less marked and she was pretty well for five months. Then, after suffering for a few days with a slight headache, she suddenly fell, unconscious, to the floor, and lay in that condition for some time. After this occurrence she was for a long time in a partial stupor, and she began to notice twitchings of the muscles of the face and eyes, more especially of the left side. About three months ago, she detected a similar attack coming on, and was able to lie down in time to save herself the fall. During this time, and until six weeks ago, she was under homœopathic treatment for 'catarrh.' She then had a third attack, much more severe than the first, in which she frothed at the mouth, and her muscles were convulsed. She was put upon anti-syphilitic treatment. She has since had no convulsions, but is much troubled by the twitching of her face and eyes, and a sensation as if her tongue and cheek were swollen. She is most of all worried by the dread of a recurrence of the epileptic attacks, so that she is very irritable and morose. Her appetite is good, and the digestive organs generally act well. She sleeps much more than in health and is nearly always drowsy. She could sleep, she says, half the day."

A Case of Dislocation of the Clavicle, Backwards and Inwards, at Its Acromial End.

Dr. A. MacGregor reports the following case in the *London Medical Times*, January 3, 1885:

On the forenoon of the 13th of December, 1882,

H. M., aged fifty, fell upon the posterior aspect of his right shoulder from a height of about ten feet. On assuming the erect posture, he attempted to raise the arm, and on doing so he, "felt something go out of joint."

I saw him on the evening of the same day, and the symptoms then were great pain about the shoulder, very slight bruising, the shoulder not so prominent as, and more rounded than on the other side. The patient could move the arm from the shoulder-joint in every direction to a very considerable extent, and with little or no pain. There was no fracture of the clavicle, and the acromion process was entire, but the outer end of the clavicle was felt to lie more upwards and backwards—more behind the acromion than usual.

I flexed the forearm, seizing the wrist with my right hand and the elbow with my left; pressing upwards with the left hand, I rotated the arm outwards, and with a grating sound the bone slipped into its place. While I held the arm in this position the dislocation remained reduced, and there was no pain; but when the limb was left to resume its original position, the bone immediately slipped back with a jerk.

Treatment.—Reducing the dislocation by flexing the forearm, abducting the arm and rotating outwards while I pressed upwards from the elbow, I fixed the limb in this awkward and uncomfortable position by means of plaster of Paris. A firm pad was placed on the top of the shoulder, and another filled the axilla. These were first fixed by carrying the plaster of Paris bandage round the joint; then the bandages were carried round the chest, shoulder, and arm by a modified figure of eight turns, and ultimately the forearm was fixed in its flexed position in the same manner, leaving the elbow uncovered behind. The chest, shoulder, and upper limb were thus enclosed in a solid case of plaster, which was removed at the end of four and a half weeks, when the joint was found to be quite strong, the bones being in perfect position. In ten days after removal of the plaster, the man was able to resume work as a common laborer.

Remarks.—The injury is unique, and I believe it is the first time that plaster of Paris has been used in injuries of this nature.

The case was at first puzzling, but the diagnosis made and the dislocation reduced, how to prevent the return of the displacement was still more puzzling.

Plaster of Paris suggested itself, and the result was very satisfactory, indeed perfect.

Ruptured Kidney—Death on Forty-seventh Day—Autopsy.

Mr. W. James Spence reports the following case in the *London Med. Times*, January 3, 1885:

Thos. C., aged 30, a laborer, was admitted under Dr. Rabagliati, about 7 a. m., on May 28, 1883, complaining of acute pain in right lumbar region. Shortly before admission, whilst engaged on works connected with railway extension, he was struck on the right flank by the revolving handle of a traveling crane, and knocked down a cutting some sixteen or seventeen feet deep.

On admission he was suffering from collapse, and was bleeding from two or three small scalp wounds. There was no other external injury. The shock passed off quickly, but the pain continued to be more or less severe for some days. An ice-bag was applied to the loins and a dose of opium given. Towards mid-day he complained of increasing pain in the hypogastric region, and soon afterwards voided a large quantity of bloody urine. During the next four days, the urine contained large quantities of blood, but on each succeeding day there was a perceptible diminution in the amount. The patient became much blanched. On June 2d large doses of iron at frequent intervals were ordered, and two days later the urine was quite free from blood. The ice-bag was left off on the 8th. He improved rapidly, and on the 15th and 16th, at his own urgent request, was allowed to get up for two or three hours each day. On the 17th the hemorrhage recommenced, and the urine continued to be mixed with blood until the 21st, when it again became clear. There was no blood on the 22d and 23d, but on the 24th it reappeared and continued to be passed in variable quantity until his death from exhaustion, on July 14th, forty-seven days after the accident. Lead, ergot, turpentine, and other remedies were tried, but they only appeared to afford temporary relief. Shortly before death he passed a large quantity of what appeared to be pure blood.

I was away enjoying my holidays when the patient died, and consequently unable to be present at the post-mortem examination. I am indebted to Mr. Phillips, the house physician, for the following particulars. The rupture was found in the medullary substance at the upper part of the right kidney. The cortical substance was apparently uninjured. The rent was filled up by a decolorized and partly organized clot. The pelvis of the kidney, the ureter, and bladder were distended with blood clot. All the other organs were healthy.

The Treatment of Lead Palsy.

Dr. Philip Zenner reports a case of lead palsy in the *Cinn. Med. News*, December, 1884, in which he says that the treatment will consist of the internal administration of iodide of potash, and the application of electricity to the muscles. The object of the iodide of potash is the elimination of lead which is still in the system. We will apply the galvanic current to the paralyzed muscles. The electrodes will be applied directly over the affected muscles, and the current continuously made and broken—for it is only when the current is made and broken that muscular contractions are produced. The faradic current would, at the present time be worthless, because it can cause no muscular contractions. But after there has been some improvement, the faradic contractility will again return, and the faradic current may then be applied, with benefit.

Rectal Anæsthesia.

It has been very truly said that there is nothing new under the sun. We had occasion to make this observation in reference to the "Rhigoline revival," and now once more we note that in the address before the Academy of Surgery of Philadelphia, Dr. John H. Packard makes the following remarks (*Med. Times*, Jan. 24, 1885):

"Let me mention, as a curious fact, that rectal anæsthesia, generally considered one of the most recent of surgical expedients, was really proposed about forty years ago, and by no less an authority than Pirogoff. Although known to Roux, in Paris, and experimented upon by other surgeons, the method was not long employed even by its inventor, although he occasionally continued to use it in allaying nephritic colic."

Correspondence.

The Revival of the Apparently Dead.

Eds. Med. and Surg. Reporter:—

December 17 surprised us of this region with a severe nor' wester, the thermometer falling in a few hours from very temperate to +10°, a very low temperature for this latitude, and very severe on outdoor animals. My wife had a handsome brood of young chickens, about as large as quails. In the evening several of them were brought to her frozen, and several were missing. She went out and soon returned with two or three badly frozen, and one apparently dead, but she thought she saw signs of life when she took it up, and designed to wrap it up by the fire and try to save it, but when she got to the fire she concluded it dead, and was about to dispose of the dead body, when it occurred to me to try an experiment suggested by a very interesting lecture delivered many years ago by Dr. B. W. Richardson on resuscitation of asphyxiated animals, which, if you conclude will be likely to do good by procuring more patient and persevering efforts to revive the apparently dead, you can publish.

In that lecture Dr. R. makes a distinction of death into glacial and pectous death, the one being only suspension of vital functions, without organic lesion, as in drowning, freezing, etc.; the other being death from some irreparable organic lesion; the first probably recoverable, the second not.

I concluded that this was a case of glacial death, that the organization was uninjured, and having no other immediate engagement, sitting by a comfortable fire, I took the chicken in my hands and commenced to induce artificial respiration by compressing and expanding the chest, which I continued for several minutes with no apparent success. My wife and daughter seemed to regard the experiment as ridiculous, and rather urged its abandonment, but I had become interested in it, and persisted. While squeezing and relaxing its chest alternately, I was thawing its feet and legs with my left hand, and they had become quite flexible. But the head hung down limp, and I perceived no sign of respiration or circulation; indeed, its beak had been for most, if not all the time, closely shut, and I had in fact forgotten the necessity of opening it. I then opened it, and found the tongue closely packed in the upper mandible, thereby hermetically sealing the trachea, so that my artificial respiration (or rather the attempt at it) had so far done no good. I now requested my wife to get its tongue out and hold it while I continued my manipulation, and in a few minutes I was rewarded with a gasp from my patient, and in many seconds, if not a minnte or two, with another, and so on, the intervals becoming very gradually shorter. I desisted from the artificial action several times, but thought it necessary to resume, until in an hour or two (for I neglected to keep time) my little patient was breathing freely; and, being kept in a basket by the fire all night, is this morning apparently as lively as ever.

Now so far as the chicken is concerned, the experiment may be of more or less value, for it might save many chickens thought to be dead, and that may be worth something on the food question. But whether it be new or not (and I do not pretend that it is), may it not be a suggestion of a more patient effort than is usual to revive asyhyxiated human beings? Dr. Richardson's lecture above referred to, especially urged this when the apparent death had taken place in cold water or cold air, for the reason that in warm water or warm air the blood much sooner coagulates, and when that occurs the death becomes pectous, and is irremediable.

Geo. D. Crosthwaite, M. D.

Florence Station, Tenn.

Narcotics and Stimulants in Old Age.

Eds. Med. and Surg. Reporter:

It is with deep regret that I find the following clinical propositions published under the name of Dr. H. C. Wood:

1. "Alcohol and opium are valuable agents to prolong the life of the aged."

2. "If you can make your aged patient an opium eater you will prolong his life."

3. "Every old man ought to take some form of alcohol at meal time." (See p. 100 current vol.)

It is now seventy-five years since I solemnly renounced the use of intoxicating beverages thenceforth and forever; and I have passed my ninetieth year, with my customary healthful vigor and mental activity—while Dr. Wood's *ward* at eighty-five "too good a patient to let die," has his physical energies narcotized by two and a half grains of opium at night, and morphia through the day, his brain case-hardened, and his intellect stultified and demented by alcohol; and thus *preserved*, is laid upon the shelf, the half-mummified relic of what he ought to have been—a *man*. Such a patient is of more value to the DOCTOR than to *himself*.

It is a melancholy fact, that many of our noblest men—men who should have been standing as venerated pillars at the distant verge of life—have succumbed to their gastronomic predilections at the age of sixty. And shall those who may survive another decade be subjected to this mummifying process, and their lives be rendered oblivious to themselves and to others? Is it strange that I should enter protest against such practice? While alcohol and opium may have their use in controlling morbid actions, they can hardly find a proper place in the healthy human system.

E. MICHENER, M. D.

Toughkenamon, Pa., 2 of 2 mo., 1885.

A Centenarian.

EDS. MED. AND SURG. REPORTER:—

I saw in the MEDICAL AND SURGICAL REPORTER of October 4, 1884, an article on "Reputed Centenarians," and as there is a centenarian that lives in my immediate neighborhood, I thought I would report the case. His name is David Gray; was born October 20, 1780, in Pellum township, Massachusetts; that making him 104 years of age last October. He is in good health, although not able to get out-of-doors. Converses easily, remembering dates and events of his past life remarkably.

The arcus senilis is but little developed, although it shows somewhat on the upper margin of the cornea. The radial artery is as soft as that of a person of the age of thirty years. As far as I can determine, there is entirely no ossification.

Mentor, Ohio.

NEWS AND MISCELLANY.

New York State Medical Society.

The seventy-ninth annual meeting of this society was held in Albany, February 3, 4, and 5, 1885, Dr. B. F. Sherman, of Ogdensburg, in the chair.

TUESDAY'S PROCEEDINGS.

The morning session was called to order at 10 a. m., and the proceedings were opened with a prayer by the Rev. J. L. Reese, of Albany.

The President's Address of Welcome

Was then read. It alluded to the absence of a number of those who had been accustomed to attend the meetings, and expressed the speaker's sense of the honor conferred upon him in his election to the office of president. The hope was expressed that a better place might be provided for the meetings in the future, and it was intimated that a hall in the Capitol might justly be placed at the disposal of the society for three days in the year. A more systematic management of the meetings was recommended—either by prolonging the meeting by an additional day, or by recourse to work in sections. Action should be taken with reference to the coming meeting of the International Medical Congress. A communication had been received from the Medical Society of the State of New Jersey that called for notice at once—presenting a proposed curriculum for students. Such alteration of the by-laws was recommended as would do away with the president's annual address, so that the time now given to it might be available for scientific work. The address closed with a feeling reference to the loss of members by death during the year. On motion, the address was referred to a committee of three, to be appointed by the chair.

A communication from the Medical Society of the State of Nebraska was read, presenting resolutions regarding the machinery by which various medical societies should communicate with each other. The purport of the resolutions was not very clear, and, on motion, the communication was referred to a special committee, for consideration and report.

Dr. Wesley M. Carpenter, of New York, presented biographical sketches of James R. Wood, M. D., LL. D., by Frederick S. Dennis, M. D.; of Willard Parker, M. D., LL. D., by William H. Draper, M. D.; of John Glover Adams, M. D., by Gouverneur M. Smith, M. D.; of Joel Foster, M. D., by Francis V. White, M. D.; all of which were referred to the Business Committee, and subsequently recommended for publication.

Dr. Carpenter also presented amendments which had been adopted by the Medical Society of the County of New York, which were referred to the Committee on By-laws; also the following resolution, which was referred to the same committee:

"*Resolved*, That any member neglecting to pay dues and assessments for two years shall forfeit his or her membership, provided he or she shall have received from the Treasurer one month's notice of his or her delinquency. Such member may be reinstated upon the recommendation of the *Comitia Minora*, by the payment of his or her arrears."

He further presented the following communication from the *Comitia Minora* of the Medical Society of the County of New York:

"1. Are all practitioners of medicine required by the laws of this State to become members of some county medical society?

"2. How can membership in a county medical society be terminated?

"3. If membership can be terminated by resignation, must the resignation of a member be accepted by the society in order to make it operative?"

Dr. W. W. Potter, of Buffalo, then reported a case of

Acute Pelvic Abscess.

The case was one of a large non-puerperal collection of fœtid pus behind the uterus, of rapid formation and accompanied with marked constitutional disturbance. The aspirator was employed when fluctuation was well marked, with result of complete relief from pain, but the patient's general condition was still precarious. Various antiseptic injections having been used with little or no result, an iodoform emulsion was introduced into the abscess cavity, after the method used by Dr. David Prince, of Illinois, and with the speedy occurrence of improvement. The patient made a good recovery. Before the attack came on, the patient had been taking cotton-root tea in large quantities, by the advice of an irregular practitioner who had diagnosticated ovarian trouble; and it was a question if this had not had something to do with causing the inflammation. The author referred to the frequency and importance of pelvic cellulitis, and credited Emmet with having done a great service to gynæcology by emphasizing the leading part played by the affection in connection with pelvic disease. As to treatment, the author advocated the radical procedure of prompt evacuation, characterizing it as "the treatment of to-day." It was only by the vagina that pus could safely escape by spontaneous opening, but there was nothing to assure us that the abscess would not break in some other direction if there was no interference with it. The necessity of antiseptic injections into the cavity was insisted upon, and they should be given by the physician himself.

Dr. W. Gill Wylie, of New York, thought that the abscess must have been due either to hæmatocele or to the access of septic material from the oviduct. He thought, too, that it was not the cellular tissue that was the seat of the collection, but the peritoneal cavity. He would prefer a trocar and cannula, with subsequent dilatation, to a knife, for opening such a collection. Caution should be observed in washing out such a cavity with so strong a solution of bichloride of mercury as a $\frac{1}{5000}$ solution. Many pelvic abscesses, especially those of the cellular tissue, were quite as apt to point elsewhere as in the vagina, and in such cases laparotomy, with proper precautions, seemed to him the proper procedure, with removal of the oviducts.

Dr. W. S. Ely, of Rochester, reported a case of what might be termed "latent pelvic abscess," in a girl of sixteen years. The collection was large when attention was first directed to the abdomen. A large curved trocar was passed into the abdomen, below the umbilicus, and out through the posterior vault of the vagina, and through the cannula a drainage-tube was passed. This "through-drainage" was speedily followed by recovery.

Dr. Bowditch related a case of pelvic abscess in a child two years of age, that had been treated like Dr. Ely's case, except that a re-accumulation of the pus led to incision and washing-out of the abdominal cavity, with the most favorable result. We are still too much afraid of opening the abdomen, as, twenty years ago, we were too much afraid of opening the chest.

Dr. David Webster, of New York, read a paper

Jequirity as a Remedy in Granulated Lids,

in which he spoke of the beneficial effects produced by the drug, but said it should be used only in cases in which considerable pannus existed, in solution not stronger than one-fourth of one per cent., making the application once a day, and not repeating it after the characteristic inflammatory reaction began to show itself.

Dr. D. B. St. John Roosa, of New York, then presented a paper on

The Removal of a Cataractous Lens in its Capsule.

If it can safely be performed, he thought that removal of the lens in its capsule would be the best means of removing a senile lens. He suggested an operation which avoids the dangers of the other operations which are generally resorted to. He had performed it in twenty-four cases. He first inserts a speculum, and, holding the edge with fixation-forceps, then with a Graefe knife a large flap of the cornea is made, and the section is half completed; the back of the knife is turned so as to rest upon the iris, and motion and pressure are made with a view of rupturing the capsele; the lens is forced out by pressure. In some few cases it has been necessary to cut the capsule. Since October last, in every case in which he has attempted it, he has been able to complete the removal of the lens with its capsule. He thinks that cocaine has contributed to the success of the operation. This procedure, he believes, does away with the dangers of the ordinary operation. He does not perform an iridectomy.

Dr. Knapp had performed the old operation, in which iridectomy was not done, some two hundred times, and he thought it was fraught with considerable danger, either at once or in the course of healing. It is possible that the use of cocaine may conduce to the successful performance of the operation without iridectomy; but he thought the results would not be as good as when the iris was nicely excised.

Dr. Webster had seen many of the cases operated on by the method of Dr. Roosa, and he had at first been prejudiced against it, but he was gradually coming to view it more favorably.

Dr. Roosa stated that he had operated on only twenty-four cases, and that there had been two total failures, which, however, had nothing to do with the lens. The point in the operation is, that there is comparatively no danger of loss of vitreous. Another important point is the fact that no instrument is inserted into the eye after the section is made.

A paper on *The Use and Limitations of Hydrochlorate of Cocaine*, by C. R. Agnew, M. D., was read by title.

Dr. Milton Josiah Roberts, of New York, read a paper on

Anatomical Geometry and Toponymy; an Introduction to the Scientific Study of Deformities.

He stated that next in importance to the notation of physical facts is the determination of their quantitative relationship to other facts—their mensuration. The measurement of anatomical angles was of direct practical importance to every physician and surgeon. For the purpose of accuracy and facility in our description and comparison of the attitude of individuals, and the position of component parts, Dr. Roberts defined a

number of toponymical terms useful in describing deformities.

For the purpose of studying the normal condition of the human body as to its form and symmetry and the extent of mobility of its component parts, so as to determine and describe pathological deviations therefrom, a uniform position of the body was suggested. This was, when the individual stood erect, resting equal weight on both feet, with the soft parts over the femoral condyles, and malleoli in contact or equidistant from each other, the feet slightly everted, and the head, trunk, and extremities forming practically an unbroken column.

Having pointed out the normal relationships of the planes of the body and limbs, the author declared that it was the business of the scientific physician to endeavor to estimate quantitatively such relationships as soon as they were recognizable. With such information at hand, the amount of pathological deviation therefrom could be determined.

Dr. Roberts suggested the use of the word *dis-astrophometry*. The angles to be measured in several important examples of pathological deviations of the planes of the body and limbs were then detailed, after which he described three mathematical instruments of his own invention for the measurement of the extent of angular deformities in the human subject.

In conclusion, the speaker declared that, with these three instruments, the orthopædic surgeon would find himself as thoroughly equipped for the accurate measurement of angular deformities of the body as the oculist is with his ophthalmoscope and trial glasses, for the measurement of errors of refraction.

Dr. T. H. Pooley, of New York, then read a paper entitled

Some Observations on the Use of Hydrochlorate of Cocaine,

with special reference to its local anæsthetic influence and its effect as a therapeutic agent in ophthalmic surgery. The methods employed had been instillations and injections into the lachrymal sac and duct.

To facilitate the examination of the eye and the treatment of its affections, it had certain advantages over atropine; but as a local anæsthetic, to precede the application of caustics, he had thus far not been pleased with the results. It had occurred to him that the drug might relieve the pain of acute glaucoma, although he had not tried it in this affection.

In conclusion, Dr. Pooley referred to two observations recently made by Weber: (1) the production of a sensation of cold; (2) augmentation of the power of the external recti muscles; facts which may influence the therapeutic use of this drug.

The paper was discussed by Dr. H. Knapp, of New York, who referred first to the discovery of the anæsthetic effect of the alkali, and second, of the mode in which it produces its peculiar influence; the latter was accomplished through the agency of the sympathetic nervous system. There were no dilator fibres in the human iris, and whatever dilatation was caused was done through the blood-vessels acted upon by the sympathetic nerves. Dr. Mittendorf had pointed out that action was accomplished through the sensory nerves, but Dr. Knapp was not quite prepared to accept that view, although it seemed quite probable that both sets of nerves were affected by the alkali. It had no bad effect on the healing of wounds.

Dr. David Webster, of New York, spoke of a case of acute glaucoma in which, at Dr. Agnew's suggestion, cocaine was used, and without effect. With regard to the effect on inflamed eyes, the anæsthesia was not so readily produced as under other circumstances. Concerning iridectomy, he had about made up his mind not to perform any more operations in cases in which the lens was transparent, because of the liability to injure the capsule and thus produce a traumatic cataract.

Dr. Sherwell, of Brooklyn, referred to a case of papilloma of the larynx, minor operations in the pharynx, and dilatation of anus for subsequent operation on a fissure. In all it was unsuccessful, except in producing anæsthesia of the mucous membrane of the pharynx.

The Chairman of the Committee of Arrangements introduced Dr. F. K. Paddock, of Pittsfield, Mass., delegate from the Massachusetts Medical Society, who also spoke of the use of cocaine.

Dr. Pooley closed the ditcussion, in which he spoke of the impropriety of attempting to perform capital operations without the aid of general anæsthesia.

Peroxide of Hydrogen.

Dr. S. S. Wallian, of Bloomingdale, read a paper on this subject. The leading physical and chemical properties of the substance were mentioned. It was said that it might take the place of ozone for many purposes, as a germicide, etc., while it was perfectly harmless in the form in which it was used in medicine. It acted by parting with a portion of its oxygen, which, being no doubt endowed with the peculiar activity incident to the nascent state, combined directly with septic substances, and thus put a stop to the putrefactive process. The author then gave a summary of its therapeutical applications, with special reference to its use in the treatment of diphtheria. Cases of carbuncle, sloughing ulcer, and septic infection (one of each) were then alluded to as having occurred in the author's practice and having been treated with the peroxide with brilliant results.

Dr. T. H. Squire, of Elmira, then described a

Case of Tubal Pregnancy,

in which rupture occurred while patient was at stool. A collection of blood in the lower portion of the abdominal cavity soon formed, and was removed with the aspirator. For some time the patient suffered from septic poisoning, and at last an exploratory incision was decided upon. So many adhesions were met with that the operation was abandoned and the wound closed. The patient at first improved after the operation, but finally sank and died nine months after the rupture had taken place. The autopsy revealed the fact that only one inch of the uterine portion of the left Fallopian tube was present; the rest, together with the right, was destroyed, or so diseased as to be scarcely recognizable. Behind the right broad ligament was an abscess containing twelve ounces of pus. As of interest in connec-

tion with the preceding paper, the speaker stated that in this case 1,200 observations had been made with the thermemeter, and in many instances the temperature was subnormal.

WEDNESDAY.

Dr. A. C. Post, of New York, read a paper

On Senile Hypertrophy of the Prostate,

in which he described the varieties of the affection, the pathology, the symptoms to which they gave rise, the methods of diagnosis, and the treatment. Special attention was directed to withdrawal of residual urine, once, twice, or more frequently, daily, by means of the catheter.

Dr. Post also exhibited a hard-rubber syringe, which he had devised for washing out the bladder, "Post's vesical syringe."

The securing of a full size of the urethra anterior to the prostate is the most important point in treatment. If the solid catheter was used, *great care* should be taken in instructing the patient how to use it properly.

In cases of large quantity of residual urine, it is not safe to withdraw all of it at the first use of the catheter. In cases in which it is very difficult to introduce the catheter, the instrument may be left in position for twenty-four or forty-eight hours. A large number of catheters were exhibited, which had been devised for overcoming the obstacles incident to local treatment, as false passages, excessive narrowing of the urethral canal, etc.

Dr. T. H. Squires, of Elmira, spoke of the treatment of prostatic retention, and he believed that in all cases the bladder could be emptied without special skill. In most cases, the soft catheter, or solid catheter of large size, can be used successfully, and in addition he would suggest gum-elastic catheters of large size and large curve.

Dr. Vanderveer, of Albany, thought that the catheter should be used from the development of the first symptoms. He preferred the silk-web catheter, and also the fountain syringe, filling the bladder to comfortable distention, and allowing it to run out.

Dr. F. M. Hamlin, of Auburn, then read a paper on

The Opium Habit,

which contained some startling statistics touching the increase of the habit in this country, as shown by the largely-increased consumption of the drug. In 1840, he said, the total quantity of opium consumed in the United States was about 20,000 pounds. In 1880, it had increased to 533,450 pounds. In 1868, it is estimated that there were from 80,000 to 100,000 victims of the opium habit in this country; now they number over 500,000. The growth of the habit has been rapid within the last few years, owing, as he thinks, to the invention of the hypodermic syringe, which has become a favorite method of administering the drug. More females than males are addicted to the use of the drug—the ratio being about three to one—women being subject to a larger number of painful ailments than men. From the time of the publication of De Quincey's *Confessions of an English Opium Eater*, in 1821, until within a few years, physicians have overlooked or ignored the serious consequences of the opium habit, and the people generally have come to look upon it as a comparatively harmless vice. It is now commanding more attention. Dr. Hamlin described the effects, immediate and remote, of the opium habit, speaking, as he said, in some degree, from personal experience, having been induced to enter upon the habit to allay the miseries of sick headache. If opium be used inordinately during pregnancy, it is apt to induce abortion, or if this do not follow, then the child is likely to be defective. He concluded his paper by presenting his method of treatment for the cure of the habit, which he describes as a sudden reduction in the quantity of opium indulged in; not an immediate and total cessation of its use, which would be injurious, but a reduction in quantity covering a week or two weeks, and accompanied with stimulants of a different kind, such as hyoscyamus, belladonna, etc., until a cure is effected.

Under this method of treatment, he thought that every case not connected with a chronic painful affection could be cured. The after-treatment is similar to that pursued in cases of typhoid fever.

A demonstration of the electric light for medical purposes was made by Dr. Lucien Howe, of Buffalo. The battery was of zinc and carbon elements connected for quantity, and the light was of rather more than six-candle power. The one shown was attached to a head-band. The cost of the apparatus was about $22. It was of Trouvé's make.

Maternal Nursing and Artificial Feeding, and their Relation to Infant Mortality,

Was the title of the next paper, by Dr. J. E. Winters, of New York. It consisted largely of statistics tending to support the common view of the great desirability of mothers nursing their own children, and in violent opposition to the employment of wet-nurses, whom the author characterized as unmitigated evils.

Dr. Bell alluded to corroborative statistics.

Dr. Ely wished to express his dissent from some of the views that the author of the paper had stated, especially in regard to the notion of the transmission of moral qualities from nurse to nursling.

Dr. Townsend, of Albany, spoke of his unsatisfactory experience with predigested milk, and various prepared foods, all of which were vastly inferior to the milk of a wet-nurse.

Dr. Jacobi thought the paper very open to criticism, chiefly from its being "sensational," at variance with the best experience, and largely founded on anecdotes.

Dr. Mittendorf, although connected with two institutions for infants, could not support Dr. Winters's views.

Dr. Winters retorted that his paper could be called "sensational" only if facts were "sensational," for he had dealt chiefly with facts.

The president then delivered the annual address, taking for his subject

Medical Evidence.

An eminent writer* says, "A doctor who knows nothing of law, and a lawyer who knows nothing of medicine, are deficient in essential requirements of their professions."

* David Paul Brown.

The object of jurisprudence is the discovery of truth; and the whole range of science, physical and moral philosophy, medicine in its widest sense, everything which experience has established or can discover, are rendered subservient to justice. While there are no limits to the sources and objects of evidence, certain rules have been adopted which restrict its admission. These rules are rigid, and too numerous and complicated to be discussed here.

An expert is selected by the court, or the parties concerned, for his supposed special knowledge or skill in particular matters to which he is to testify, or make a report embodying his opinions.

I cannot better define the duties and requirements of the expert than to quote in full from Elwell:

"Extra knowledge on questions of science, skill, trade, business, or other matters requiring special knowledge, qualifies the person thus informed to give *opinions* in courts of justice. This is contrary to the general rule that the witness must confine himself to facts, and leave the conclusions of those facts to be determined by a court or jury under oath. An opinion is the judgement which the mind forms on any proposition, statement, theory, or event, the truth or falsehood of which is supported by a degree of evidence that renders it probable, but does not constitute absolute knowledge, truth, or certainty.

"These opinions or conclusions of judgment which make up such opinions of experts, are the same in substance as the verdict of a jury or judgment of a court, which is nothing more than the opinion of such jury or court as to what is established by the facts in the case. This conclusion or opinion, in the latter case, is given under the sanction of an oath; so is that of an expert. There is this difference, however, in the two cases. The court or jury are under oath while they are making up their opinions upon the facts in the case, and these facts upon which the opinion is predicated are also submitted to the minds of counsel and parties. The facts are also given by the common witness under oath, upon which the jury or court makes up an opinion. The expert, on the other hand, comes to the results constituting his opinion, which is to be received in evidence, from his own private study, observation, and reflection. He is not under oath when he weighs his facts, and however anxious he may be to arrive at correct conclusions, he is not under the significant and impressive obligation of an oath to do so; and though the facts upon which the witness' opinion is based may be called for by counsel, yet from the very nature of the case it is not to be expected that the jury or the court will understand them."

Importance of Medical Evidence.—No man, be he professional or layman, is properly qualified to appear as a witness without some knowledge of his duties, and the rights pertaining thereto.

The medical man, as a witness, is subjected to the most rigid criticism as to what he says, how he says it, and why he says it, and also to all the influences that may have a bearing upon it. This criticism comes not only from the opposing counsel, but also from the party by whom he is called; and he is thus placed, as it were, between two fires, from which he is fortunate if he escapes without being wounded, and especially so if he is an important witness.

Ignorance and deception may triumph in the sick-room, where it is not cross-examined, while in open court it can find no protection, and must be exposed. The medical witness must understand the general rules of evidence, without which he is sure to meet with interruptions and chagrin, if not disgrace. No one should presume to enlighten the court and jury in a difficult case, unless he is able to do so. He may be compelled to attend court, like other witnesses, but no witness is compelled to testify to what he don't know, and if he is not qualified, the safe and honorable course is to acknowledge it.

Duties and Responsibilities of Medical Witnesses.—While works on medical jurisprudence must be studied and analyzed, it is not in them that the medical witness will find the directions he needs to prepare him for the important duties of making up and giving opinions, that are to be received as facts by the court and jury.

In a report made to the American Medical Association, the writer, in speaking of the medical witness, uses the following language: "If, however, he concludes to form an opinion and testify, there are certain rules and regulations which he should adopt, not only to give force to his testimony, but for his own protection.

"1. He should listen attentively to the testimony, as to all the facts in the case, and avail himself of every authentic means of forming a correct opinion.

"2. He should studiously guard against being biased, either by popular clamor, or because he is called by one side rather than the other.

"3. The medical witness is not to take into consideration the influence which his testimony may have on the prisoner at the bar, or the case under consideration.

"4. The expert is called to testify as to the bearing of the testimony given, and though he may have his own doubts of the truth of the testimony, yet, if it stands unimpeached, he must receive it as truth.

"5. A medical witness should not assume the province of the jury.

"6. The medical witness should have his mind fully prepared, before taking the stand, as to what he can testify to, and his reasons, if they are required."

The medical witness is rarely called upon to testify to facts, as gathered by the exercise of his senses; but to give the deductions drawn from the facts given by others. These facts may be new to him, and may be drawn from any part of the wide domain of science; yet he may be called upon to give an opinion, with no time for reflection, or for reference to authority; while counsel who manage the case have plenty of time to familiarize themselves with the authorities, and with all the evidence bearing upon the case. The common witness has simply to state the facts within his personal knowledge, but the medical witness must know the facts first, constituting the case upon which his opinion is desired; he must apply to these facts his special knowledge, and from this reach a conclusion in his own mind, and give this opinion to the jury. He should never permit himself to be drawn into a discussion while upon the stand.

Before answering a hypothetical question, the witness should weigh every word and see that there is no confusion or contradiction of terms or language, and then confine his answer closely to the supposed case. The courts require a hypothetical question to contain only facts that are in the case, and the expert says what they prove scientifically.

If the question involves an impossibility, as it sometimes does, the witness should decline to answer until a definite case is put.

THURSDAY.

Dr. S. O. Vanderpoel, of New York, read a paper entitled

Does Quarantine Protect?

The probability of the occurrence of cholera renders this question pertinent. The dissemination of the disease is attributed to the Mecca pilgrims. Its natural home is Calcutta. The measures enforced to prevent its spread are inspection during the period of migration, at an island in the Red Sea, and at the seaport of Mecca.

Owing to sanitary inspection during the past eight years, the spread of cholera by the Mecca pilgrims has been prevented. The recent epidemic in Egypt was attributed to the fact that Great Britain had evaded the quarantine regulations. If quarantine be effectively carried out, cholera could not occur. But if cholera once acquire a foothold—quarantine is useless. Then local hygienic measures are to be used. Cholera can only come to this country from Europe.

If a thorough medical inspection of individuals and of clothing coming from distant ports be made, if suspicious cases be isolated and their excretions disinfected, it is almost impossible for the disease to extend to this country.

If a vessel comes to our shores with cholera on board, it should not be allowed to reach the mainland. Passengers should be disembarked and kept under close observation for ten days, and ten days after the last case has appeared, they may be allowed to proceed. There are only five ports in this country at which steerage passengers are landed, viz.: New Orleans, Baltimore, Philadelphia, New York, and Boston. A rigid system of inspection should be begun at once, and it will be our own fault if cholera reaches our shores.

Dr. H. I. Bowditch, of Boston, fully endorsed the views expressed by Dr. Vanderpoel.

The following resolution was then adopted and ordered to be transmitted to the President of the United States:

Resolved, That it is the sense of the New York York State Medical Society that the United States Government should, in view of the probable importation of cholera poison during the present year, promptly take steps to enforce proper sanitary measures at foreign ports where the disease exists.

OFFICERS FOR THE ENSUING YEAR.—In accordance with the report of the Nominating Committee, officers were elected as follows:

President—Dr. A. Vanderveer, of Albany.

Vice-President—Dr. A. C. Post, of, New York.

Secretary—Dr. W. M. Smith, of Syracuse.

Treasurer—Dr. C. H. Porter, of Albany.

Censors—Southern District, Dr. F. A. Castle, Dr. G. H. Fox, and Dr. David Webster, of New York. Eastern District, Dr. Joseph Lewi, and Dr. N. L. Snow, of Albany, and Dr. LeRoy McLean, of Troy. Middle District, Dr. A. Churchill, of Utica, Dr. L. Griffin, of Binghamton, and Dr. R. Frazier, of Camden. Western District, Dr. T. Dimon, of Auburn, Dr. M. G. Kittenger, of Lockport, and Dr. D. Little, of Rochester; for the College of Medicine, Syracuse University, Dr. I. N. Goff, of Cazenovia.

Committee of Arrangements—Dr. S. B. Ward, of Albany; Dr. W. S. Ely, of Rochester; and Dr. E. L. Partridge, of New York.

Committee on By-Laws—Dr. W. C. Wey, of Elmira; Dr. H. G. Piffard, of New York; and Dr. W. M. Smith, of Syracuse.

Committee on Hygiene—Dr. E. V. Stoddard, of Rochester; Dr. F. C. Curtis, of Albany; Dr. A. N. Bell, of Brooklyn; Dr. G. J. Fisher, of Sing Sing; Dr. E. Hutchinson, of Utica; Dr. H. Bailey, of Albany; and Dr. J. P. Creveling, of Auburn.

Committee on Legislation—Dr. D. Lewis, of New York; Dr. S. B. Ward, of Albany; and Dr. F. R. S. Drake, of New York.

Committee on Ethics—Dr. A. Jacobi, of New York; Dr. A. Matthewson, of Brooklyn; and Dr. J. W. Whitbeck, of Rochester.

Committee on Prize Essays—Dr. W. W. Potter, of Buffalo; Dr. W. S. Ely, of Rochester; and Dr. H. R. Hopkins, of Buffalo.

Committee on Publication—Dr. W. M. Smith, of Syracuse; Dr. C. H. Porter, of Albany; and Dr. A. Mercer, of Syracuse.

Medical Society of the State of Pennsylvania.

This body will hold its thirty-seventh annual session in the city of Scranton May 27, 28, and 29. As the programme of the meeting must be distributed at least one month prior to the meeting, all who desire to present papers at this session are requested to forward to the undersigned the title and a brief abstract of the same not later than March 15, 1885.

It should be remembered that no voluntary paper is allowed to occupy more than twenty minutes in reading.

W. B. ATKINSON,
Permanent Secretary.

Changes in Hospital Staffs.

Drs. Hunt and Packard take the places of Drs. Morton and Levis as attending surgeons at the Pennsylvania Hospital. Dr. Horwitz becomes resident physician in the same institution in place of Dr. Trotter, who has served his term.

At the Presbyterian Hospital, Dr. Hunter Robb takes charge of the surgical ward, and Dr. W. J. Simpson takes the place of Dr. Hamaker in the medical ward, the latter taking a similar position in the University Hospital.

Lawson Tait's Opinion of American Medicine.

In his "American Notes," this distinguished English surgeon tells his colleagues of the Birmingham Medical Society that the general summary of his visit to the United States and to Canada may be briefly put in the statement that no Englishman can obtain a reasonably full grasp of how the world is moving, or of the numerous phases of life, medical and surgical as well as others, until he has seen life across the Atlantic.

Information Wanted.

Reports of surgical operations upon the gall-bladder or ducts, whether previously published or not, are desired for a contribution to an important work; and all facts connected with them will be thankfully received by J. McF. Gaston, M. D., Atlanta, Ga.

Personal.

Dr. Mary A. Swayze has been elected Vice-President of the Schuylkill County (Pa.) Medical Society.

Items.

—In the *Quarterly Journal of Inebriety* for January, 1885, Dr. Robert Lawson, of England, publishes an interesting paper on "Brain Disorders from Alcohol."

—In the *Annals of Surgery*, January, 1885, Dr. Lewis A. Stinson publishes an interesting paper on "An inquiry into the origin of the use of the ligature in the treatment of aneurism."

—In the *Lancet*, January 19, 1885, Dr. Arthur E. Barker reports a case of excision of the kidney for ruptured ureter and urinary abscess, in a child aged three years and eight months; recovery.

—Dr. Osborn was recently elected to membership in the Academy of Medicine of Cincinnati, e making the fourth female member. These u lady physicians are fairly active members of e academy.

—We learn that the Illinois Central Railroad will furnish an excursion train of Pullman parlor cars for the physicians and their families who think of attending the meeting at New Orleans, to leave Chicago on Saturday evening, April 25, at 9 o'clock.

—The Medical Department of the Columbian University, Washington, D. C., has opened its doors to women during the present session, four of whom have already matriculated. This step was not taken without due deliberation, and the male students do not seem to be disturbed by the introduction of a new element into their midst.

—At the meeting of the New York Academy of Medicine, January 15, 1885, Dr. C. C. Lee, chairman of the committee on education, reported that, after a full and careful consideration of the resolutions referred to at the last meeting, the committee deemed it inexpedient for the Academy to take any action at present in regard to the question of a State Board of Medical Examiners.

—A Baltimore cooking school was opened by a number of subscribers desirous of securing a supply of trained cooks for that community, January 19. A building has been erected at a cost of $5,000, and capable of accommodating a class of seventy-five to one hundred persons. It is said to be the first distinctively cooking school erected in this country.

—At a recent meeting of the Philadelphia County Medical Society, Dr. H. Leaman pesented a dynamometer, by which he claims he can measure the value of that part of a uterine contraction which is available in the expulsion of the fœtus. It is intended to measure the expulsive force of the uterus minus the resistance in succession of the uterine cervix, pelvic walls, and perineum, and might be called a parturiometer. He thinks it will prove valuable as a means of determining when instrumental interference becomes necessary.

—Dr. Robt. J. Lee, in a clinical lecture upon infantile syphilis (*Lancet*, October 18, 1884), calls attention to the fact that too much reliance must not be placed upon the presence or the history of symptoms in the mother. He states that the most common occurrence in married women is that they are free from all symptoms. The next most common is some of what are known as tertiary symptoms. The least frequent are active secondary symptoms. In the condition of the father must be sought the explanation of the varying symptoms presented by both mother and child.

—A painful instance of the danger of using anæsthetics by unskilled hands was furnished a short time since by a dentist in Paris. A gentleman died suddenly whilst M. Duchesne was extracting his tooth. M. Brouardel, after a most careful necropsy and examination, states that there were not any natural causes of death, but that it ensued from an excessive inhalation of an anæsthetic. The brain, heart, and intestines were sent to the toxicological laboratory. It has been ascertained that the extraction was bloodless; therefore, death must have occurred before the operation was effected.

—A report having been made in the newspapers that the Garfield Memorial Hospital was about to close its doors for want of funds, a statement has been published that its financial condition is not so depressed as has been represented. It certainly is in need of funds, but it is out of debt. Since its opening, in June, 1884, 115 patients have been received, of whom 79 occupied free beds. The Surgeon-General of the Army, Dr. Murray, speaks unqualifiedly in approval of the management. The ladies who have undertaken to procure funds for the institution are still sanguine of being able to provide the necessary ways and means for its support.

QUERIES AND REPLIES.

MESSRS. EDITORS:—

Please explain what is meant by a four per cent. solution, and oblige, W. B. J.

Ans.—A four per cent. solution is where four parts of a substance by weight is dissolved in ninety-six parts of water by weight.

MESSRS. EDITORS:—

In case a woman applies to a physician for an abortifacient, is it ethical and legal for him to give her some inert preparation, and thus preserve the life of the unborn babe from further attempts, by a slight deception?

ANXIOUS.

Ans.—We suppose it is legal, and perhaps it is ethical; but we think that a square refusal to do anything, real or pretended, toward accomplishing such a purpose, is the wisest course.

MARRIAGE.

WILLIAMS—JEWETT.—January 29, 1885, at Macon, Ga., Dr. Howard J. Williams and Mattie Kittie, daughter of Mr. Henry L. Jewett.

THE

MEDICAL AND SURGICAL REPORTER.

No. 1460.] PHILADELPHIA, FEBRUARY 21, 1885. [Vol. LII.—No. 8.

ORIGINAL DEPARTMENT.

LECTURE.

CLINICAL LECTURE ON DISEASES OF WOMEN. DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROFESSOR T. GAILLARD THOMAS, M. D.

Gentlemen: Before I commence the regular work of the hour, let me again make a remark, and enforce it with an illustration, which I have already incidentally had occasion to make to you; and that is, that no one ought to engage in the study of medicine with the view of making it his profession for life unless he has a good physique and enjoys ordinarily good health. This morning I had just finished a lengthy surgical operation when I was called by a physician to see a lady who at the end of seven and a half months of utero-gestation was suddenly seized with violent pains and profuse hemorrhage. On making an examination, I found two very important conditions present, viz., placenta prævia and an arm presentation. In addition, the pelvis was so deformed that I could not pass my arm through it, so that altogether the case presented a most discouraging combination of circumstances. The blood was gushing out of the uterus in torrents, and there was nothing to do but to attempt version as soon as possible. On account of the contraction of the pelvis, however, it took me a whole hour to accomplish this, though I was working as hard as I could all the time. In consequence of the prolonged and severe exertion, I was utterly exhausted; and although several hours have elapsed since then, the exhaustion still continues, so that I feel scarcely able to appear before you. If I had not been of a robust constitution, I could not have borne the necessary fatigue; and I wish to impress upon you, therefore, that cases are very liable to occur in practice when human life depends not so much on the skill as on the physical strength of the physician.

Gonorrhœa in the Female.

Our first patient to-day is Mrs. Lizzie O'B., a native of Ireland, and twenty-nine years of age. She has been married five years, and has had two children, but no miscarriages. Her last child was born three and a half months ago, and she has continued to nurse it since that time. In answer to our inquiries, she says that she has been sick for about a fortnight with something which she got from her husband. The latter, it seems, told her that he himself had some trouble about his privates, which he contracted "through the use of an unclean instrument." The principal symptoms of which she has complained are, pain in the back, a profuse purulent discharge from the vagina, and a constant desire to pass water. Almost every fifteen minutes, she says, she has to pass a little, although the act of urination is not accompanied by burning sensations.

Here is a very short and simple story. The husband, who frankly acknowledged that he had gonorrhœa, communicated the disease to his wife two weeks ago, and the usual symptoms have resulted. On making a physical examination, we find upon separating the labia vaginæ that the parts within have actually the appearance of red flannel, so completely congested are they, and that they are hot to the touch. About the

meatus urinarius there is a decidedly granular congestion, and from the urethra is constantly flowing a stream of creamy pus. The whole vagina is bathed with the ichorous material, and it is also flowing from the os uteri, although here it is not of such a creamy character as that coming from the urethra. It is not always that we get such a clear history of gonorrhœa in the female as in this case. Gonorrhœa in the male is not ordinarily a very severe disease; but occasionally it is disastrous in its results, and I have personally known of one death attributable to it, the inflammatory process having implicated the bladder, and thence extended along the ureters to the kidneys. In the female, however, gonorrhœa, as a rule, is a much more serious affection; not so much in the dangerous character of its acute symptoms as of the results, since it is exceedingly apt to be followed by ovaritis and inflammation of the fallopian tubes, which sometimes renders the performance of Tait's operation necessary. Still, while it is of a serious nature, it is not so much so as some of the other affections peculiar to females, such as pelvic cellulitis.

In some cases vulvitis, vaginitis, urethritis, cystitis, endo-cervicitis, metritis, salpingitis and ovaritis, all result in turn. Therefore it is a disease which requires careful treatment in its earlier stages, so as to avoid, if possible, such an unfortunate train of evils. In the present instance I have advised this patient to put herself under the care of a competent physician, and will recommend to the latter that he should personally make injections into the vagina and into the urethra of a solution of the bichloride of mercury of the strength of 1 to 2000. In addition to this, I think it would be advisable to inject the bichloride solution into the canal of the cervix itself, and from time to time to place against the os uteri a pledget of cotton saturated with the same, and provided with a string for its easy removal. Usually in these cases the patient is given by her physician one injection, which she is told to inject into the vagina night and morning. As a fact, however, the injection gets into only about one-half of the vagina, leaving a large portion of the canal untouched, and never reaching the urethra or the cervix. Consequently, such a course of injections cannot effect a complete cure. There may be some temporary improvement; but there is sure to be a "relapse," because the inflamed mucous membrane not reached by the injections goes on pouring ont its ichorous discharges. In this way the disease may become chronic and last for months, or even years. If we are going to cure it, therefore, we must attack it in its most secret lurking places; and this is to be done in the manner which I have described. As to the husband's story that he contracted the disease from an "unclean instrument," that is no doubt to be regarded as altogether chimerical. There is a possibility, of course, of such a thing having occurred, but it is exceedingly remote.

Uterine Fibroids.

Our second patient is Mrs. Margaret T., 27 years of age, a native of Ireland, and unmarried. She says that she has been complaining for about ten months, and that the first thing which she noticed was a severe pain in the right side of the abdomen. Menstruation has occurred regularly during the last ten months, but lasts much longer than formerly; the discharge continuing for about ten days. The flow, however, is not excessive on any one day.

This is a very meagre history; but it is sufficient to direct our attention to the pelvic organs, and a physical examination reveals abundant cause for the symptoms complained of. In any case, therefore, where there are any symptoms referable to the pelvis, I cannot urge upon you too strongly the advisability of making such an examination before venturing to prescribe for the patient. The woman lying on her back, I found on passing my finger into the vagina that the uterus was a little drawn to one side, and to the right of it I discovered, with the aid of conjoined manipulation, what I now show you upon the blackboard, viz: two large round masses, one above the other. Each of these rolled very freely upon the other, but neither of them could be removed without dragging the uterus along with it. This was proved beyond question by the fact that a sound placed in the uterus was very perceptibly rocked by the movement of the masses.

This question now comes up, What are these masses? In the first place, they cannot be accumulations of fæcal matter in the *caput coli*, because they are too symmetrical in outline, and because they are movable. Fæcal tumors, it is well for you to recall, are never movable. They are sometimes, however, as large as a child's head at term, and I have known very experienced physicians to mistake them for cancerous growths in the pelvis. In the second place, they might possibly be supposed to be deposits of lymph, resulting from inflammatory action, or, in other words, phlegmons. Phlegmons, however, also are never movable, and they are never insensible to pressure, as these tumors are found to be. It would also be highly

improbable that there should be two of them together, as is the case here. In the third place, are they ovarian cysts or growths? No; because they are solid, and solid ovarian tumors are exceedingly rarely met with. But, even were such not the case, this diagnosis would be excluded by the fact that there are two tumors here.

It is reasonable to conclude, therefore, that these growths are uterine fibroids. They are of the sub-peritoneal variety, and from the past history of the case we infer that they are growing very rapidly. The prognosis in this instance is not as satisfactory as in some others of the same affection, which I have had occasion to show you during the course. Some of you will perhaps think that I give a different prognosis in every case of uterine fibroid that I have to deal with; but a man who has a routine prognosis and a a routine treatment for all cases of this character is a charlatan. In the last case that I brought before you, the growths were considerably larger than here, and the patient was 42 years of age, and as the menopause was to be expected in three years, I prophesied with confidence that she would have no more trouble after that time, and advised that nothing whatever in the way of treatment should be attempted. With our present patient, however, matters are very different. She is now only 27, and hence has nearly twenty years to go before the change of life. In addition, the tumors have already grown very rapidly, and there is a baggy feel about them which indicates with considerable certainty that this rapid process of development is going to continue. Unless something can be done, therefore, to arrest this growth, the prognosis is very unfavorable. It is now about eight months since these fibroids were first detected by the physician who has been attending the patient, and he thinks that in that time they have doubled their size. If, then, this rapid growth should continue, what will they be at the end of eighteen or twenty years?

From the premises in the case of the woman 42 years old, my deduction was that she should be let alone, because she was rapidly approaching the menopause. From the premises here, however, my deduction is that it is our duty to interfere, though not immediately, by operation.

We will first try to stop the hemorrhage. There are, as you know, drugs which have the effect of causing contraction of the blood-vessels, and typical among these are the ergot of corn and the ergot of rye. For the next three months, therefore, I will recommend that ergot should be administered systematically; but if by the end of that time we find that these growths have increased in size instead of diminishing or remaining stationary, and that the hemorrhage at the menstrual period lasts for fourteen days, instead of ten, I would advise the removal of the ovaries by Hegar's operation. By doing this, we would simply accomplish what nature practically does at the time of the menopause; and, as far as the function of menstruation is concerned, we would place the patient at the age of forty-seven instead of twenty-seven. If there is nothing malignant about these tumors (and there is no reason to suppose that they are of a sarcomatous character), the patient would cease to menstruate after the operation, and the uterus would soon become forgotten by the economy. In such cases the blood-vessels become atrophied and sometimes atheromatous, and masses like these, connected with the uterus, shrivel up. It would not be a safe proceeding to remove the tumors themselves by operation. I trust that in two or three months from now we may again have the opportunity of seeing this patient, and we can then decide more satisfactorily as to what is best to be done in her case.

You know that it has been said that menstruation does not depend on ovulation. This physiological question is an interesting one; but it is not important, for in the very large majority of instances in which I have operated I have found that when I remove the ovaries it puts a stop to menstruation. Personally, therefore, I feel convinced that menstruation does depend on ovulation. In a few rare instances I have noticed that menstruation went on after the ovaries were removed; but when this has been the case, the menstruation has not been the important physiological process it was before. It is simply a species of metro-staxis, resembling epistaxis in its character, and any fibroids of the uterus that exist shrivel up just the same as if the menstrual flow had permanently ceased.

Cervical Catarrh afd Retroversion, with Enlargement and Prolapse of the Ovary.

Our last patient to-day is Mrs. Mary B., 32 years old, and a native of the United States. She has been married ten years, and has had two children, but no miscarriages. Her last pregnancy occurred eight years ago, and she says she has not been well for five years. The chief trouble is pain in the back and abdomen, and she suffers also from profuse leucorrhœa. She is regular as to her monthly periods, and has no worse pain at such times than at others. The headache of which she complains, and which is not constant,

she says does not, therefore, seem to be associated with disorder of the menstrual function. The patient, as you perceive, has the appearance of a perfectly healthy woman; but still she has had something the matter with her in reality ever since her last child was born. Making an examination here, I found the uterus in a state of marked retroversion, and under it there was a round, soft, and sensitive mass. The cervix had a cicatrix upon it, showing that it had been operated on for laceration during labor, and its whole surface was in a state of granular degeneration; the condition being what was formerly called ulceration of the cervix. The diagnosis is plain. When the last child was born, eight years ago, the cervix was torn through to the vaginal junction. In consequence of this accident the uterus, instead of undergoing normal involution, remained in a state of subinvolution, as it is called, and on account of its unnatural size and weight became retroverted. The laceration of the cervix, by the exposure of the glandular structure of the part which it caused, gave rise to a constant ichorous discharge, which was poured from the torn surfaces, and which was similar in character to the irritating discharge which flows over the upper lip of a child suffering from chronic nasal catarrh. This condition of affairs has in time affected one of the ovaries, and the organ, enlarged and in a state of irritation, has become prolapsed below the uterus.

Formerly the condition of the uterus here met with was called chronic metritis. This was cutting rather than untying the Gordian knot; but now we try to untie the knot.

The uterus, after being torn during labor, suffered from subinvolution, which gave rise to a chronic hyperplastic condition, with catarrh of the cervix. The retroversion is simply a symptom. In treating such a case, the first thing to be done is to restore the laceration of the cervix by operative procedure, and this has already been successfully accomplished here. We must then restore the uterus to position, and apply appropriate local treatment to the granular cervix.

—In the *Lancet*, January 17, 1885, Dr. T. Wharton Jones publishes an article entitled "Remarks on the Circulation of the Blood." Historical notice of the discovery that the veins of the bat's wing, which are furnished with valves, are endowed with heart-like rhythmical contractility, whereby the blood is assisted onward in its course to the heart. A protest against efforts made to ignore a crucial fact in nature."

THERAPEUTIC ACTION OF COCAINE IN A CASE OF DIPHTHERITIC CONJUNCTIVITIS.

BY WILLIAM S. LITTLE, M. D.,

First Chief Clinical Assistant, Eye Department of the Jefferson Medical College Hospital, Philadelphia.

The use of muriate of cocaine in a case of diphtheritic conjunctivitis has afforded an opportunity of observing a therapeutic action of the drug on the inflamed mucous membrane of the eye and the tissue underlying it, similar to the influence of the drug, observed on the inflamed mucous membrane of the nose, which was first reported by Dr. F. H. Bosworth, of New York city, "A new therapeutic use for cocaine, as to its influence on the nasal mucous membrane."* The freedom from hemorrhage when operations on the eye are performed, the drug being used for its local anæsthetic effect, indicates a therapeutic action very valuable when the conjunctiva is inflamed. The severe type of inflammation associated with purulent, gonorrhœal, and diphtheritic ophthalmia calls for a radical reduction of the œdematous lids and chemotic conjunctiva; so as not only to prevent pressure on the cornea and infiltration of it, but also to enable the lids to be everted for the thorough cleansing of the conjunctival sac and application of remedies. A division of the outer canthus heretofore has frequently been required in such cases to accomplish these purposes. The history of the following case and method of treatment illustrate the therapeutic action of cocaine in reducing the œdema of the lids and chemosis of the conjunctiva. The type of the inflammation existing in the mucous membrane of the eye of the case observed, this deposit rarely exhibiting itself at this portion of the tissue, and the good result obtained by the use of cocaine, suggest the value of its use when the mucous membrane of the throat is similarly affected, as is so frequently the case.

When intra-ocular disease is accompanied with chemosis of the conjunctiva and œdema of the lids, the use of cocaine will be found to have a like effect, as in the case to be described, and as has occurred in my practice.

A very successful result has followed the employment of the drug in manipulating the canals of the body covered with mucous membrane, but the claim for the use of the drug has been largely for its anæsthetic effect, and not so much for its therapeutic action on the tissues, namely, reduc-

*The Medical Record, November 15, 1884.

ing the œdema of the tissues underlying the inflamed mucous membrane.

A case of severe conjunctivitis was seen at the Eye Department of the Jefferson Medical College Hospital on December 18, 1884, in a man aged thirty-seven, stating that on December 16 the lower lid of the right eye became slightly swollen.

December 17, the eye felt as if a foreign body was in it; when seen, the upper and lower eyelids of the right eye were markedly œdematous, chemosis, and ecchemosis of ocular conjunctiva, especially below, secretion from the palpebral portion of it, cornea clear, iris normal; had suffered no constitutional disturbance. A case of gonorrhœal ophthalmia was judged to be developing, though contagion from such a source was denied. The patient was informed of the severe type of the disease, precautions as to protecting the other eye, and danger of infection to others. A weak solution of silver was applied, atropia instilled, and ice-cold applications to be employed, the eye to be kept free from accumulated secretion. Absorbent cotton was used for cleansing the parts, as it removes the secretion so easily, and can be immediately destroyed by burning; pads of it laid on ice render the cold application easy for the patient and very effective, where this is constantly required.

December 19. The patient was unable to leave his bed, and sent for me. Found he had vomited during the night, had a hemorrhage from the nose, a high fever, and depressed condition. Pain was very severe in the right eye; lids very œdematous, conjunctiva chemotic, secretion from the lids not profuse, but a membrane had developed on the upper and lower lids on the conjunctival surface; cornea clear. Any attempts at manipulating the eye were very painful; upper lid could not be everted. While waiting for medicines, the use of a two per cent. solution of cocaine was decided upon, so as to relieve pain and allow the handling of the parts; a few drops instilled between the lids accomplished this in five minutes; but the most marked and interesting feature resulting from the use of the drug was the influence upon the œdematous lids; at the middle of the lower eyelid a depression occurred in the tissues, as if pitted with the finger, gradually increasing in area, so that in the twenty minutes from the time the drug was employed the upper and lower eyelids were free from the œdematous state; the same impression was made on the ocular conjunctiva, especially below where it was most markedly chemotic and infiltrated with blood. Applications to the eye were made with hardly any objection on the part of the patient. The severe constitutional symptoms called for appropriate remedies.

The following day, the œdema of the lids was found not to have returned; slight chemosis of conjunctiva, cocaine being used twice to relieve the pain and allow sleep. Carbolic acid, one grain to the ounce, was used as a wash; a stronger solution, five grains to the ounce, which has been recommended by Dr. G. H. Burnham,* of Toronto, in the gonorrheal and diphtheritic types of conjunctival inflammation was found to be too irritating and painful. The left eye was free from trouble, and protected by a bandage.

On the fifth day the cornea was slightly cloudy; on the sixth day became infiltrated, perforating at its outer margin, aqueous humor escaping; the cornea to the inner side became so symmetrically swollen and globular, that I thought the crystalline lens might have ruptured its capsule and escaped into the anterior chamber. Prof. Wm. Thomson saw the case with me, suggesting eserine in place of atropia and lime-water, as a wash. The constitutional symptoms were still very marked.

Dr. Morris Longstreth kindly examined a portion of the detached membrane from the right lower eyelid, finding the microscopical picture characteristic of a diphtheritic membrane, and not of a gonorrhœal type. The membrane became less distinct after the eighth to the tenth day, the tissue bleeding when touched. After the cornea became involved cocaine was discontinued, desiring all the blood possible to reach the cornea for its maintenance, hot water at the time was not acceptable to the patient, but in a day or two was found to be more desirable, as the conjunctiva became less inflamed.

December 29th I found that during the night a temporary nurse had given the patient ten drops of a two-grain solution of eserine in place of iron, despite proper labeling of the bottle and instructions of the regular nurse to give the patient nothing.

Dr. Dennis, who saw the case very shortly after the dose of eserine, $\frac{1}{24}$ of a grain, states that the spasm of the lids was severe, slight twitching of the mouth and slight movement of the hands, but no severe constitutional disturbance; chloral was given. On the following day I found that the left eye, which had been free from trouble, was affected in the following way: Swelling of

*The American Journal of Ophthalmology, November, 1884.

the lids at the inner canthus, some pus present, slight chemosis in ciliary region to the temporal side; the pupil showed no evidence of eserine; leeching and cold applications prevented any further effects. The severe spasm of the eyelids had no doubt forced material from the right eye into the nose and up the left lachrymal canal, into the left conjunctival sac. If the case had been of a gonorrhœal type, severe infection of the eye would no doubt have followed, the escape was no doubt due to the subsidence of the diphtheritic condition of the right eye, and the abatement of the constitutional symptoms. Atropia was kept in the left eye for some time.

The patient was in bed for three weeks. During the third week the right eye gradually improved, being twice leeched. The sloughy comatose condition of the cornea decreasing under pressure, and the cornea clearing; anterior and posterior synechiæ are present.

At the end of a month, find right eye free from any conjunctival secretion, ocular conjunctiva slightly congested, a central ulcer of cornea, with synechia rapidly healing. Left eye is free from irritation, is hypermetropic, 2 D., ophthalmoscopic picture normal.

An entire loss of the eye is the rule in these cases. The saving the eyeball in this case was no doubt due to the impression made on the œdematous lids so early in the case, and the reduction of the chemotic conjunctiva, which has heretofore been largely controlled by leeching. The case demanded, during its violence, the constant assistance of a nurse.

CASTRATION FOR HYSTERO-EPILEPSY. (BATTEY'S OPERATION.)

BY J. G. BROOKS, M. D.,

Of Paducah, Ky.

Mrs. McN., of an exceedingly nervous temperament, aged 27 years, has borne three children, and had one abortion at two months. I attended her in last confinement, November 18, 1880. Labor was very rapid, lasting not over an hour from first symptoms. She had but two real expulsive pains, and the child was delivered while she was in a convulsion.

I attended her at intervals for minor complaints from this time until July, 1882, when I was called to treat her for uterine hemorrhage. I found the womb enlarged, with the cervix and os extensively eroded. This condition I treated with compound tincture of iodine and cotton pessary saturated with glycerine. Had her use also the hot water douche twice a day. Under this treatment the womb reduced in size and the erosions healed rapidly, but she would have a profuse leucorrhœa a few days before and subsequent to the menstrual period.

From this time she began to suffer great pelvic distress with pain in ovarian region. This increased until it was a decided oöphoralgia.

She would have these attacks at irregular intervals, which were always preceded by a very great desire to copulate. This desire became more and more intense, until it amounted to nymphomania, and would be followed by regular hystero-epilepsy of the worst form.

This state of affairs with her was unchanged until January, 1883, during which month she was free from all of her annoyances, save the venereal appetite, which was nearly uncontrollable.

February, just before the menstrual period, the pain became very intense in the ovaries, and passed off with the most severe attack of hystero-epilepsy I ever saw. A large dose of morphine and atropia put her profoundly to sleep; and when she awoke, the flow had come on and she was easy for a few days. From this time on she would have nymphomania, oöphoralgia, and hystero-epilepsy, until July, 1883, when she had a free menstruation, and felt some improvement until August, just before her period, when she had an explosion, as it were, of all the old symptoms, but in a more aggravated form. At this period she failed to menstruate and soon began to show enlargement of abdomen, which caused some of the scandal-mongers to make inquiries if all were right. She was interrogated as to the chance for her to be pregnant. She avowed there had been no chance for her to have gotten in any such condition, and was perfectly content to wait and let time prove her clear of the charge.

From this time until the following February and March I did not see her often, as she had learned to use the hypodermic syringe and to ward off these attacks of oöphoralgia, hystero-epilepsy, etc., by the free use of morphine.

In February, 1884, she became very much worse, and I was sent for to see if I could not do something for her. I found her as I had left her in August, only worse, from a broken-down constitution—I might say, a perfect wreck from the use of morphine. There was no use of attempting to withdraw the opiate at this time, for the pain was so intense when she was not narcotized

that there was no such thing as bearing it. I now advised the removal of the ovaries, and she readily consented, but preferred waiting until spring.

She continued the morphine, enlarging the dose from time to time until she was taking twenty grains *per diem*.

I left home the latter part of April for New York, on my way to Washington to attend the meeting of the American Medical Association. While I was in New York, I was invited by Dr. T. G. Thomas to see him operate on a similar case. I was allowed not only to see the operation, but also to see the wound dressed and the patient put to bed; all of which gave me additional knowledge and confidence, which was of great value to me when I came to operate.

Soon after my return I made ready to operate, and on the 18th of May, 1884, Sunday, between 11 and 12 o'clock, the time set by my patient, I performed laparotomy in the presence of Drs. Saunders, Maxwell, Becker, Thompson, Rivers, and Wheelis, and assisted by Drs. Kay, Davis, and Cowgill. After the patient was thoroughly under ether, an incision three inches long was made in the median line, the peritoneal cavity readily entered, the ovaries exposed and found to be normal in size. I will state just here that I had repeatedly failed to feel either ovary, notwithstanding the abnominal walls were very thin. The ovaries were removed, with the tubes, after Mr. Tait's plan.

The silk ligature was used, the stump cut close and returned into the abdomen. Very little blood was lost. The peritoneal cavity was cleansed, and the abdomen closed with silver sutures, the wound dressed, and patient put to bed before the clock struck 12.

She came from under the anæsthetic readily, with but little nausea, and felt very comfortable, slept well the following night, and was free from pain. We continued the usual amount of morphine for a few days, but soon began to use less, finding that it could be done without inconvenience. At no time after the operation did the temperature go above 99½°, pulse 96, respiration normal.

On the fifth day one-half of the sutures were removed, and on the sixth all were taken away, and union was found to be perfect throughout the wound.

At no time did she have any tympanites. Her improvement was continuous and perfect, and on the twenty-fifth day after the operation she went driving. From this time on, the morphine was rapidly withdrawn, until, after about ten weeks, the syringe and morphia were taken away. During the seventh week she suffered with gastralgia together with decided hysterical symptoms, which were not controlled until the cold-water douche was suggested to me by my friend Dr. Rivers. I orderered that when these hysterical manifestations presented, she be stripped and set in a a tub, and a stream of cold water be poured down her back until relieved. She bitterly opposed this measure, but she got the douche as directed. She had but a few spells afterwards. She has been perfectly well since August 1, 1884, and had no morphine.

Since the operation she has had no leucorrhœa, no venereal excitement, or any other annoying symptoms except hysteria at the time above mentioned.

The antisepsis used at operation consisted in the thorough cleansing of the hands of those to handle instruments, and the wound. The silk, instruments, sponges, etc., were washed in carbolized water, and the wound was dressed with corrosive sublimate, cotton and gauze.

Dr. Wilhelm Tauffer, of Buda-Pesth, after reporting twelve cases of castration operated upon by him, says in his conclusions, that castration, with proper care, is not attended with any great risk; that both ovaries should be removed, even if the disease be limited to one, lest the remaining gland become diseased in the same way as its fellow; that it is generally desirable to remove the tubes with the ovaries; that hystero-epilepsy is curable by castration; that it is an open question as to how far disease of the female sexual organs influences the development of certain psychoses, and whether such psychoses are curable by castration; that the condition laid down by Hegar, that the ovaries should be distinctly felt before their extirpation is attempted, is an impracticable one.

Dr. Robert Battey, of Rome, Ga., reports in the August number, 1883, of the *Virginia Medical Monthly*, ten castrations, with eight ovariotomies, performed by him, and not an unsuccessful case. All, or nearly all, of his castrations were for öophoralgia, nymphomania, hystero-epilepsy, insanity, etc., one or more of these symptoms attending each case.

This case of mine is reported for what it may be worth to statistics or otherwise. From the results I can claim this much: (1) That it goes to prove that öophoralgia, together with the associated psychoses, are curable by the removal of the ovaries. (2) It goes also to prove that the teach-

ings of Hegar, viz., that the ovaries should be distinctly felt before the operation, should not, necessarily, be heeded.

Then, aside from the operation, we prove that the opium habit can easily be broken up, after all physical suffering has been removed; especially is this true if we can get the hearty coöperation of the patient, as I did in this case.

HOSPITAL REPORTS.

LECTURES ON INSANITY.

Delivered at the University of Pennsylvania,

BY CHARLES K. MILLS, M. D.,

Lecturer on Mental Diseases in the University of Pennsylvania; Consulting Physician to the Insane Department of the Philadelphia Hospital; Neurologist to the Philadelphia Hospital; and Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic.

Reported by WILLIAM H. MORRISON, M. D.

LECTURE II.

Hallucinations—Illusions—Delusions—Imperative Conceptions and Morbid Propensities—Insanity of Manner—Moria—Incoherence—Delirium.

GENTLEMEN: Before taking up the various forms of insanity, I wish to call atfention to a few points in general symptomatology. Of course, much time could be occupied in a consideration of this topic, but I shall discuss only a few of the more important general symptoms; some of those which it is necessary to understand, in order to have clear ideas when considering the special forms of insanity.

I shall then first briefly treat of the hallucinations, illusions, and delusions of the insane.

It is difficult to define the terms which are used in the study of mental diseases, for the very reason that the terms themselves indicate, really or apparently, paradoxical conditions. Thus an hallucination has been defined as an unreal sensation. It is a false perception of the senses. The individual believes he sees something which does not exist in fact; or he mentally hears, tastes, touches, or smells something which has no physical existence.

An illusion is a perverted sensation or a perverted perception—a false interpretation of a real sensorial perception. Something which has a real existence is supposed by the victim of illusion to be something else. The sound of thunder is interpreted to be the voice of God, not in a figurative, but to the individual in a real sense. In the same way a post of wood may, from its color or some other peculiarity, be regarded as a piliar of gold.

A delusion is, in general terms, a false belief. This statement is, however, far from giving you all the knowledge that you require in reference to the definition of a delusion. An hallucination may or may not be a delusion, and the same may be said of an illusion. That is to say, any one may have an hallucination which he recognizes as such, and it therefore does not become a delusion, because he does not persistently believe in it, or perhaps not at all, except at the moment of its first appearance before him. I shall give some of the different forms of hallucinations, illusions, and delusions.

A man has an hallucination of hearing, who supposes that he hears a voice threatening to destroy him. This is a common form of insane hallucination. Another hears a celestial voice. Another is touched or affected, it may be, by what he terms electricity; he has that peculiar sensation which in the popular mind is associated with electricity; he feels an electric shock. This is another common form of hallucination. Occasionally all the senses may be involved in the hallucination, but this is rare. A woman may hear the voice of her persecutor, she may imagine that she sees him in the twilight, that a peculiar sulphurous odor is emitted by him, and that she tastes poison which has been placed in her food and drink. Commonly the hallucinations affect a single sense or two or three together.

A notional delusion is one unconnected with the senses, that is, one which involves neither an hallucination nor an illusion. Thus, a man imagines that he is Jesus Christ, or a woman holds that she is the Queen of America, or the wife of Lafayette. Another imagines that he is made of glass, or that his legs are of cork or lead. Sometimes the delusion has reference to what is supposed not to exist. Some important organ may be believed to be absent.

Clouston gives a series of the delusions which he found in about one hundred female patients, the most of which I will repeat for you. Their simple repetition will give a good idea of the varying character of the depressive delusions of the insane.

They were delusions of general persecution, of general suspicion, of being poisoned, of being killed, of being talked about, of being defrauded, of being pregnant, of being destitute, of being very wicked, of imminent death, of the soul being lost (which is not an uncommon form of delusion in melancholia), of having a bone in the throat, of having lost much money; that she was about to be buried alive, that she was about to be murdered, that the flesh was boiling, that the head was severed from the body, that murders took place around her, that she was tempted by the devil, that she was possessed by the devil, that she had committed the unpardonable sin, which is another common form of melancholic delusion. Other delusions were of identity being lost, of being covered with vermin, of letters being written about her, of property being stolen, of children being killed, of the legs being made of glass, of being chloroformed, of having committed murder, of being cut up, of being a man. Sometimes the reverse is true, and a man imagines that he is a woman. A well-known case of this kind was in the Philadelphia Hospital for a long time. The man believed that he was a woman, and insisted on dressing as a woman, and at the balls always danced with the men. Still other delusions were, of having contracted venereal disease, of being confined for debt, and of having committed suicide.

A delusion may be a sane delusion or an insane delusion, and this distinction often involves very

important questions. Thus the question of legal responsibility for murder might depend upon the decision whether a delusion was sane or insane. A sane delusion is simply a false belief, out of which the patient can, by ordinary means, be reasoned. Not long ago, I had a good illustration of a sane delusion. A patient came to my outdoor hospital service—a woman who had been depressed in health for some time. She told me that she saw sights at night on lying down, and she described with great particularity the appearance of an animal, which rose up before her. She also told me that it appeared more vividly on getting into a certain position. She knew that it was unreal, and was able to reason herself out of it. She described the animal with such detail, and was so honest about it, that there could be no question about her having seen it. The delusion always remained a sane delusion, and under treatment she recovered.

An insane delusion is defined by Spitzka as "a faulty belief, out of which the subject cannot be reasoned by adequate methods for the time being;" by Kiernan as "a firmly-fixed, baseless belief, whose inherent falsity can be demonstrated." These are two of the best definitions of which I have knowledge.

Occasionally, insane patients will be met with who can temporarily be reasoned out of and made to see that they are the victims of a delusion, but will again pass back into the delusive state. A patient will sometimes, for a purpose. say that he knows that he is laboring under a delusion, insane though he be. Thus we read of a patient who was put under a shower-bath for a short time, then brought out and asked if he still believed that such and such things were so. The patient replied that he did. He was ordered back to the shower-bath, and the same process was repeated, until at last his faith, *apparently*, *at least*, became weaker, and he acknowledged that he no longer held the ideas which he had previously entertained. Certain points will help in determining whether a delusion is insane or sane. It is necessary to compare the individual with himself in studying the question as to the existence of an insane or sane delusion. An insane delusion is usually adhered to vigorously and vehemently, in spite of all the reasoning that can be brought to bear.

The terms genuine and spurious delusions are applied by Spitzka and others to explain different forms of delusions among insane persons. A genuine delusion is one which the insane patient firmly holds, that is, one which is part and parcel of the insane condition, and has been created by the patient himself. A spurious delusion is one which is imposed on the patient, or one which he imitates or assumes. A very erroneous notion is that which many physicians, and more lawyers and laymen, hold—that an insane man cannot simulate insanity, that he cannot even simulate delusion, and yet be insane. A grandiose, paretic dement put into a ward with a number of other patients will sometimes have gathered around himself a number on whom he has, temporarily at least, imposed his own delusions.

Delusions are systematized or unsystematized. Next to the recognition of the difference between sane and insane delusions, the question whether a delusion is systematized or unsystematized, is in the present state of the science of psychiatry of the highest importance. The Germans in particular have paid attention to this matter. Spitzka, among American writers, has most clearly expounded the difference between systematized and unsystematized delusions, and to him I am indebted for most of the views here expressed on this subject. If you examine the older psychiatrical writers, you will find no reference to this matter. This question of systematization is now a clearly defined point in the study of this branch of medicine. At the same time, I do not wish you to be misled into the idea that a delusion that is systematized can always be easily separated from one that is not. A delusion which is systematized is one that the patient explains, elaborates, or defends. It is one that has a certain appearance of logic about it. It is really, however, pseudo-logic. It is a delusion which has a more or less complete organization, and which is held more or less persistently.

An unsystematized delusion is one which has no organization. The general features of a systematized and unsystematized delusion may be the same; that is, they may both be of a depressing character as in melancholia, or of an expansive character as in some varieties of mania, but the unsystematized delusions are delusions that the patient cannot explain, which he does not attempt to defend, and for which he gives no logical, illogical, or pseudo-logical explanation. A paretic dement tell you that he is worth $150,000, as in a case which I saw a short time ago. I said to him, "My man, if you are worth so much, why do you not live in better style?" He could give no answer. A paretic dement, again, may tell you that he is the most important man in this city, and that anything that he says will be done; but if he is asked why he does not use his power, he will branch off into something else, without giving any reason. He may say that he is one hundred feet high, but when a man of ordinary height stands beside him, he can give no explanation of his evident littleness. So in a case of melancholia, the patient hears the voice of the enemy, now speaking from the wall, now from some other direction. He does not attempt to account for these voices in any special way. He simply hears them, they depress him, and that is all.

A patient with systematized delusions may tell you that he is worth a great deal of money, but he will endeavor to explain how he has made it. If he is asked why he does not use it, he will have an elaborate story about its being in a trust company, and that he is preparing the necessary papers to secure it. If he assumes that he is General Grant, the Emperor of Russia, or some other great personage, he will have certain ideas, and try to perform acts in consonance with his assumed position. A lunatic with a systematized delusion of persecution by voices will explain how these voices reach him. One of the most beautiful illustrations of a systematized delusion that has ever come before the Philadelphia public, was that of a well-known man in this city. For many years this man has been insane, and his is perhaps as clear a case as is to be found in any asylum. This man believes

that he is persecuted by voices, and he supposes that these persecutions are carried on through some electrical or other agency, which is unknown at present to science. In order to defend this delusion, he has written two elaborate and somewhat rhetorical pamphlets. In his pamphlets he refers to the telephone and phonograph, and says that a person who a few years ago would have said that he could hear voices a hundred miles distant would have been considered a lunatic. He does not deny that others do not hear these voices, but he hears them, and he defends his delusion.

Imperative conceptions (and here again I am indebted to Spitzka) are perhaps, strictly speaking, elementary or rudimentary delusions. They cannot be readily defined. They are certain peculiar mental phenomena which gain control over the individual, and which tyrannize him for the time being. These imperative conceptions lead to the performance of acts which are called imperative acts or morbid impulses. Often a monomaniac who for a number of years has had imperative conceptions, may end with a true delusive state. You have the morbid impulse to steal, which gives a special variety of insanity known as kleptomania; or the morbid impulse to set on fire, giving pyromania; or the imperative conception which leads to the morbid impulse to kill, or to commit suicide, etc. These conceptions tyrannize the individual; he can not rid himself of them, and he is forced to commit the acts which he conceives to be imperative under these circumstances.

An imperative conception is only an isolated conception. It is one which exists only for the present, but usually to come again sooner or later. A man to-day may have an impulse to kill, and he may not have it again for years. A morbid propensity persists to a greater or less extent for a long time. It is an exaggeration or perversion of a normal propensity.

These morbid propensities usually consist in a perversion of the sexual instinct or a perversion of the desire for food. Wonderful instances of sexual perversion have been written about in times gone by and also recently. It is likely that many of the frightful murders of which we read are committed by lunatics of this kind, who have some terrible morbid propensity. Such persons violate the person of the women they have killed either before or after the commission of the murder, and not only do that, but cut their victims into pieces. In some cases they have done this and eaten portions of the bodies afterwards. Often bodies are taken from the graves and violated by people with these peculiar perversions. There are other no less horrible propensities of this sort.

Some of the many varieties of monomania are simply mild instances of imperative conceptions or mild morbid impulses. It is, I think, not wise to erect a great variety of forms of insanity upon matters of this kind, but it is necessary to have a general idea of these peculiar manifestations in order to appreciate the cases which we have to present to you.

Kiernan* says, "There are certain terms frequently used though found in but few English text-books, as 'Insanity of Manner' and 'Moria.'" Insanity of manner as described by him, "denotes a condition often a symptom of oncoming insanity in recurrent cases, but most frequently associated with chronic forms of insanity, especially in those patients who carry on a profession without manifesting (to the casual observer) any symptoms. The patient with insanity of manner is likely to make little grimaces without apparent cause, to indulge in motions of the fingers, to use a constrained tone of voice. It is one of those conditions which once seen is easily recognized, but which seems to defy description. Moria simply implies a flight of ideas, and is a very convenient term introduced into psychiatry by the Germans."

Incoherence and delirium are terms also often used in speaking of the insane. Hammond* describes two kinds of incoherence:

1. That in which the words used in speaking or writing are without proper relation to each other.

2. That in which the ideas are without logical arrangement, or are incompletely expressed.

The same author defines delirium as "that condition in which there are illusions, hallucinations, delusions, and incoherence, together with a general excess of inability, an inability to sleep, and acceleration of pulse." Illustrations of incoherence and delirium will be given under special forms of insanity.

Medical Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

A Case of Possible Bony Union after Intra-Capsular Fracture of the Femoral Neck,

was the title of a paper read before the Philadelphia County Medical Society, November 19, 1884, by John B. Roberts, M. D., surgeon to St. Mary's Hospital, Philadelphia, wherein he remarked that much has been said against the possibility of osseous repair occurring after intracapsular fractures of the neck of the thigh-bone. It is probable that this teaching has induced more than two-thirds of the general medical profession to believe that bony union of such lesions never occurs. Careful investigation of cases and specimens by competent surgical observers has conclusively demonstrated that such belief is erroneous.† Bony union does occur, though not frequently. In my opinion, moreover, its non-occurrence is to some extent due to the violent and unjustifiable manipulation to which injured hips are often subjected by reason of the attendant's ignorant desire to demonstrate crepitus and preternatural mobility. The diagnosis can usually be made with reasonable certainty without the development of these symptoms of fracture. Therefore, it is unnecessary and improper to imperil the future usefulness of the limb merely to arrive at an absolute diagnosis. In cases of doubt, it does no harm to

†See paper by Dr. N. Senn, in Trans. American Surgical Association, vol. i., 1883.

treat the case as one of fracture, even if none exist; but violent manipulation, by tearing connecting bands of periosteum or detaching impacted fragments, greatly reduces the probability of union.

Union *may* be bony, and the function of the joint perfectly or almost perfectly restored: if not bony, the bond of union may be a very short fibrous one, giving as good functional result as osseous repair. Hence, the surgeon should treat his cases as if he expected a good cure; for it is impossible to say that a given patient is one in which no attempt at union will take place. Non-union of intracapsular fracture of the hip is, it is true, often found. I have in mind now a case where the autopsy showed no attempt at even fibrous union. Let us not expect this, however, as a rule, for we may thus be led to neglect proper therapeutic measures. Specimen No. 1130[15] of the Pennsylvania Hospital Museum, taken from the patient referred to above, between eighteen and nineteen weeks after the injury, is a good illustration of non-union. It was a transverse fracture at the junction of the head and neck of the bone. Specimen No. 1130[20], from the same Museum, on the other hand, is here shown you; it is described in the Museum catalogue as an intracapsular fracture firmly united; and by longitudinal section shows bony union. The specimen belongs to Dr. T. G. Morton, and was removed from a patient, aged sixty-seven years, twelve years after the accident that caused the injury. There is some evidence of impaction near the base of the neck; and it is perhaps *possible* that part of the line of fracture extended without the capsule. Of this we have now no definite evidence, as the ligaments were removed in preparing the specimen. This cast of a specimen is from the Mütter Museum of the College of Physicians, and represents an impacted fracture of the femoral neck in which there was *inversion* of the leg. The patient was under the care of Dr. Conklin, of Ohio.

I have made these prefatory remarks to introduce the clinical history of a patient who has now good use of her limb subsequent to an intracapsular fracture, although treatment was abandoned shortly after the receipt of the injury. She has probably a short fibrous union; possibly a true bony one. In either event, however, the result is gratifying, and teaches that such cases should not be looked upon as necessarily hopeless in respect to union.

She is a German, 78 years old, and was admitted to my ward in St. Mary's Hospital on August 30, 1884, after falling from a street car. The resident surgeon believed there was no fracture at the hip; but on my visit I considered that the position of the limb and the patient's age pointed to intracapsular fracture of the neck of the femur. On taking hold of the leg and making rotation without violence, I felt distinct crepitation. At once desisting from further manipulation, I ordered permanent extension by weights, and lateral support by sandbags, to be the treatment. Within four days, incontinence of urine, the development of a superficial bedsore, and the debilitated condition of the patient, showed me that there was danger of the aged woman dying. I accordingly ordered the resident surgeon to discontinue the fracture dressing, so that the patient's buttocks and back could be kept clean, and the bedsore properly dressed, telling him that no union of the fracture was likely to occur, and that we must endeavor to save life by tonics, stimulants, and food, and the prevention of further bedsores. I gave a similar prognosis to my polyclinic pupils who saw the case. Ten days later, that is, two weeks from the time of injury, another incipient bedsore was noticed on the buttocks. The hospital notes of this date say I ordered that change of posture be frequently made, and that she sit up as soon as possible. Six days subsequently she was sitting up in a chair. I am unable to say whether she got out of bed previous to this date or not. The bladder symptoms gradually improved, she soon sat up all day, and on October 4, five weeks after admission, it is recorded that she was walking on crutches. On October 26 she was able to walk a little *without* crutches, though she did not do so much. She continued to gain in activity until her discharge on November 2.

The result was so unexpected to me, for no restraint of motion at the hip was attempted after four days, that I almost mistrusted my diagnosis, and concluded that possibly the resident surgeon's original diagnosis was correct. I had made no investigation of the condition of the limb since she began sitting up. A few days before her discharge, however, I put her in bed, and with my colleague, Dr. Keen, examined her. The leg was strongly everted, as in intracapsular fracture, immediately after the injury, and she was able to invert it only so far as to make the toes nearly vertical. She could raise the leg, however, and lay it across the other, or carry it outward; and, indeed, appeared to have every motion of the joint, except full inversion, though she stated it was a little stiff when walking. She had no pain. The everted leg, therefore, made the correctness of my diagnosis an established fact. Here, then, in a woman of 78 years, was obtained union and a useful limb, despite the absence of treatment. In the face of such a result, treatment should always be attempted, and not abandoned unless circumstances, such as arose here, demand its discontinuance. Well-directed treatment may certainly be expected to make many good cures, if no treatment will occasionally give so excellent a limb.

DISCUSSION.

Reported by G. Betton Massey, M. D.

Dr. O'Hara: "I assent to the views put forth by Dr. Roberts. I recall a case of a gentleman of 79 years of age, injured on a railroad car in motion, moving his body at the same time to get out on the platform.

"A distinguished surgeon pronounced it as hopeless for cure, and, as the patient was so aged, advised nothing to be done for the repair of the fracture. It was diagnosed by both of us as an intracapsular fracture.

"Sand-bags and extension were applied. The patient readily co-operated, and barely moved for eight weeks. He had good health, though so old, and to my astonishment he walked in eight weeks without a crutch. There was very little difference to be noticed between the two limbs, except a slight eversion of the affected one. He

used the limb without any trouble until he died, seven years later. The man, for his age, was remarkably healthy, and this might have been other than a fracture of the neck, but those present examining it at the time could make no other diagnosis."

Dr. John H. Packard: "From Dr. O'Hara's statement as to the shortening in his case, I should scarcely think him warranted in claiming it as probably one of bony union of an intracapsular fracture.

"I regret that I came in so late as to miss the report of Dr. Roberts' case, and the earlier portion of his remarks upon it. The subject is one which has greatly interested me, and I have examined with care all the reports of cases claimed as bony union, and all the specimens accessible to me. [Dr. Packard then illustrated by diagrams on the blackboard the structure of the neck of the femur, as shown on vertical section.] In all cases of fracture wholly or partially extracapsular, there is a long point or spur of bone, extending down close to the lesser trochanter. When such degeneration takes place, the stricture becomes weaker and less marked, and there is a certain amount of fatty change; under these circumstances the bone may give way even under slight stress, near the head, and across the axis of the cervix. Now all the cases claimed as of bony union of fracture of the neck of the femur within the capsule, with one exception, are open to the explanation that the fracture was really in part extracapsular; and that the lower portion of the cervical fragment, after union had taken place, became absorbed, so that the head sank down against the intertrochanteric portion of the distal fragment.

"The exception was in a specimen presented by Dr. J. M. Adler, in 1869, to the College of Physicians of Philadelphia; it was referred to a committee consisting of Dr. A. Hewson, Dr. John Ashhurst, jr., and myself, and we decided, after careful study, that it was an example 'of genuine bony union of an impacted intracapsular fracture of the cervix femoris.'

"A year or two since I had the opportunity of examining one of the specimens claimed by the late Dr. R. D. Mussey, of Cincinnati, as of this character, and found the long point of bone, above described, still distinctly marked.

"With regard to treatment of fractures of the cervix femoris, I think we are seldom justified in leaving the cases to nature; only, in fact, when the age and debility of the patients, the occurrence of bed-sores, and the restlessness sometimes met with in old people, make the chance of a good result too small to warrant subjecting them to the discomfort and even risk of confinement with extension.

"Some years ago I exhibited to the Academy of Surgery a man who, when sixty-two years of age, fell backward over a pile of boards, fracturing the neck of the left femur. He was tractable and of fairly temperate habits; I treated him at his home, with extension by weight and pulley, and after the first week made him sit up daily in bed. Although I told him he would probably remain always a cripple, he recovered completely, and walked well, even up and down stairs, at the fourteenth week. When brought before the Academy, he had no limp whatever, and could stand on or move either leg indifferently; there was actually nothing, except slight perceptible thickening, to show on which side the injury had been.

"About ten years ago I was called to a young man of about twenty, who had been thrown from the high driving-seat of a wagon, and sustained a fracture of the neck of the thigh-bone. Dr. Nancrede, who aided me in the dressing, and myself, determined the nature of the injury under ether. The man recovered so that within two months he was driving his wagon, as well as ever.

"I think that, while we can never confidently promise much in these cases, we ought never to despair, and never be satisfied with anything less than the best attainable results. Unless the unfavorable conditions before mentioned are present in a most decided degree, an attempt should always be made to institute effective treatment."

Dr. Levis: "I think Dr. Roberts a little too confident of our ability to make a differential diagnosis in these cases. It is certainly sometimes impossible to do so without making the manipulations which he condemns. In obscure cases, when a diagnosis is important, I place the patient with the face down, and carry the limb back as far as it will go. Normally, this distance is but slight, but fracture of the neck of the femur allows much greater motion. It is with regret that I put a patient through this manipulation. The best method to make a differential diagnosis between the two forms of fracture, is by rotating the limb. Normally, the great trochanter rotates in an arc with a radius of the full length of the femoral neck; if there is intracapsular fracture, this radius is but slightly diminished; while there is scarcely any radius in extracapsular fracture, because the centre of rotation is the long axis of the femoral shaft."

Dr. Packard: "I feel bound to protest against the employment of needless force, or, indeed, of any violence or rough handling, in the diagnosis of fractures. In the case of the hip, if crepitus is once elicited, that should suffice; there should be no further testing nor demonstration of it, lest the fragments be brought into worse position."

Dr. Levis: "I never feel assured of the real lines in any case. If the cause is trivial, and there has been no fall upon the trochanter, it is probably intracapsular. If there has been a severe fall upon the trochanter, it is highly probable that it is extracapsular. I do not recall what was my feeling on this point in the case Dr. Baldwin alluded to, but from his remarks would say it was extracapsular."

Dr. Addinell Hewson: "I have had experience with both intra- and extracapsular fractures, and have a very good specimen of bony union that was my father's.

"In a case at the Pennsylvania Hospital, I first demonstrated the value of the contrivance known as the "Lover's Telegraph," for conveying the crepitus to the ear. I have used it frequently, and am satisfied that many cases can be demonstrated by it otherwise difficult of recognition. The surgeon is in too great a hurry usually. In a majority of cases we may have union with some shortening, by using N. R. Smith's anterior splint, keeping the limb so suspended in a semi-

flexed position at both hip- and knee-joints, and allowing the patient to move in the bed without danger of disturbing the coaptation of the fragments or the occurrence of bedsores."

Dr. W. S. Forbes: "The point alluded to by Dr. Levis—the radius of the arc of rotation—is important. An illustration of its value occurred under the care of the late Dr. Joseph Pancoast, when he diagnosed intracapsular fracture in a young man of 27, owing to a lessening of the arc of rotation on one side. The other surgeons present at the consultation doubted it, having in mind Sir Astley Cooper's saying that he had never seen a case occurring under 30 years of age.* The man died in a week, of mania-a-potu, and the specimen is now in the museum of the Jefferson Hospital, showing fracture of the neck within the capsular ligament."

Dr. Packard: "I think that Sir A. Cooper must have been aware of Mr. Stanley's case, that of a boy of 18, which occurred at St. Bartholomew's Hospital about 1830." †

Dr. A. V. Meigs: "I recall a case, treated by Dr. Levis, at the Pennsylvania Hospital, three years ago. The patient now walks without a stick. She is 90 years old."

Dr. Roberts, in closing the discussion, said: "The discussion this evening shows us that the result of treatment of this accident is much more favorable than has been heretofore taught.

"I am glad to know that Dr. Packard believes in the occasional occurrence of bony union. In such cases bony union probably results because the periosteum covering a portion of the neck is untorn or because the fragments are impacted. If there is impaction, you of course have bony union favored for mechanical reasons.

"The third point I wish to make is that it is shown, by the possibility of impaction and untorn periosteum, that violent manipulations for differential diagnosis should not be allowed. Should I suffer from a personal infliction of the accident, there would be a very small amount of handling done by my attendant, if I were able to remonstrate."

Meeting December 17, 1884.

Dr. Joseph B. Potsdamer reported

A Case of Poisoning from Thirty Grains of Chloral Hydrate.

J. R., æt. 43, in moderately fair health, has for the last three years been a victim of insomnia, caused by business troubles. For the relief of the sleeplessness, he used the bromide of potassium, until marked bromism was produced, and he was advised by a physician to discontinue it. This was about a year ago. He then began to take chloral hydrate. He would buy ten cents' worth of the drug, which, I am informed by several druggists, would be a drachm. This quantity he would divide into four doses, and take one about once in ten days or two weeks, as occasion would demand. On or about the 5th of October, he bought at a drug-store a drachm of Schering's chloral hydrate dissolved in a half-ounce of water, which was labeled "teaspoonful at a dose." On retiring that night, he took half of the above-mentioned solution, that is, two drachms, containing thirty grains of the drug. This, he said, had very little effect upon him.

On the sixteenth of the same month, he retired at about 8 p. m., taking the remaining portion of the solution, that is, the other thirty grains. About 11 p. m., his wife found him in a profound sleep, and, as there was a rattling of mucus in his throat, became alarmed and sent for me. I reached the patient's bedside soon after. Having been informed of the circumstances of the case, I at once proceeded to examine the patient, and found him in the following condition: Thoroughly unconscious; pupils contracted; respirations shallow, slow, about eight per minute; breathing stertorous; fauces full of mucus, giving rise to the rattling; pulse barely perceptible, was unable to count it; heart-sounds weak, but regular; extreme coldness of face and extremities.

Having understood the family to say the drug had just been taken, I administered twenty grains of the sulphate of zinc in a glass of water, at 11:45 p. m.; applied cold flagellations to the body, and gave strong coffee and whisky.

October 17, 12:15 p. m. Patient not having vomited, gave twenty grains of powdered ipecac in a large quantity of hot water; continued the coffee, and made efforts to rouse the patient; at 12:45 p. m., the emetics operated; this was followed by temporary dilatation of the pupils. 3 a. m. Able to rouse the patient; pupils react slightly to light. 6 a. m. Patient, on being aroused, talks rationally, but drops off to sleep again; pulse perceptible, one hundred beats per minute; respirations normal, eighteen per minute. 1 p. m. Patient sat up for a little while; still very drowsy. 8 p. m. He has been awake since 5 p. m.; complains of headache.

October 18, 10 a. m. Has had a good night's rest, and feels perfectly well. The treatment previously described, excluding the emetics, was continued throughout the night.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting December 26, 1884, Dr. Henry Beates in the chair.

Dr. James B. Walker reported a case of

Ulcer of the Stomach,

which came under his observation at the clinic of the Woman's Hospital, January 13, 1881, suffering from a *third* attack. The first had occurred three years before, and was accompanied by hæmatemesis. After an interval of about a year and a half a recurrence of all the symptoms, except the hæmatemesis, brought her to the clinic, where gastric ulcer was diagnosticated, and she rapidly recovered under treatment. The third attack, the one under consideration, had existed nearly two months before she applied at the same clinic for relief. She was in a condition of profound emaciation and exhaustion, presenting a cachexia

[The Publication Committee have permitted Drs. Forbes and Packard to add the following notes to their remarks in discussion.]

*"It (fracture of the neck of femur) very rarely occurs under fifty years of age; and dislocation seldom at a more advanced period—although there are exceptions to the rule, for I have myself once seen this fracture at thirty-eight years of age, and a dislocation of the thigh at sixty-two." Astley Cooper, Surgical Essays, part ii., page 35, second edition, London, 1820.

†It was published in the "Medico-Chirurgical Transactions," vol. xviii., as read May 27, 1833.

suggestive of malignant disease. The previous history aided in the exclusion of malignancy, and on account of the serious condition of the patient, and the necessity for more than ordinary care, she was admitted into the wards of the hospital.

At first all foods gave intense pain, even in minimal quantity, and water administered in teaspoonful doses was immediately rejected. All feeding by mouth was suspended, and enemata of beef tea alone administered. For twenty-three days not a particle of food was given in any other way. Then milk in minute quantities was tentatively administered, in alternation with minute doses of beef tea, and after three or four days, the stomach proving able to perform its functions without pain or uneasiness, the enemata were discontinued and the patient discharged, her health being completely restored. The medicinal treatment consisted in blistering the epigastrium, the administration of large doses of subnitrate of bismuth at four-hour intervals during the day, and a quarter of a grain of nitrate of silver at bedtime. Inunctions of sweet almond oil were used towards the close.

The author spoke of the value of oil of turpentine in 15 or 20 drop doses in sweetened water at intervals of two hours, in cases of hemorrhage from ulcer of stomach, and mentioned one case in particular where it had apparently saved life when all ordinary methods had not only failed, but seemed to aggravate the symptoms.

Discussion.

Dr. A. V. Scott had used rectal alimentation in a similar case with success. Cinchonidia sulph. in 20 grain doses was given with the food.

Dr. E. E. Montgomery did not hear the whole report of the case, but was reminded by the concluding remarks of two cases seen the previous year. The first was an old gentleman suffering from gastric catarrh and gastralgia—the latter appearing both before and after meals. Under rigid diet the pain after food ingestion was controlled, but that occurring in the empty condition was not lessened. Food was taken frequently. After several months of suffering, the patient was carried off by an attack of pleuro-pneumonia. The post-mortem appearances indicated commencing carcinoma. The kidneys were not granular.

The other case was confined to bed six months, with constant vomiting of food in a sour condition. All food was rejected with equal impartiality. Dr. Bartholow being called in consultation, found evidences of specific lesions, which had been denied by the patient. After using mercurials in vain, however, another consultation developed the suspicion that we had a case of hysterical vomiting to deal with; and, under appropriate treatment, the patient quickly recovered.

Dr. L. Brewer Hall desired to bear testimony to the value of turpentine in hemorrhage of the stomach. The good results of its use are immediate, and it is also of value in pulmonary hemorrhages. The oil of erigeron may be used instead, and is more acceptable to the taste.

Dr. Henry Beates, Jr., asked Dr. Walker if he still looked upon the micaceous appearance of the skin as an evidence of carcinoma, and if so, if it would not have been of service in the diagnosis of one of the cases related.

Dr. Walker, in closing the discussion, said he had seen but two cases with the micaceous skin which were not carcinomatous, one being a case of pernicious anæmia. He looked upon it as only confirmatory. The use of oil of erigeron as a pleasant substitute for turpentine as a hæmostatic, was suggested by the late Dr. Geo. B. Wood, but as the accuracy of taste of the suggestor was doubted, the speaker had taken a dose of it on a patient's complaint several years ago, and had not recovered from it yet.

In the cases simulating gastric ulcer the resemblance is interesting. The dejecta are more frequently sweet than acid in such cases. In unsuspected cases of carcinoma in plethoric subjects, the peculiar appearance of the skin alluded to may be the only indication present of the real nature of the case.

As regards Dr. Scott's case, the course pursued seemed to embody all that was necessary. Total rest of the affected organ is generally sufficient, though bismuth may be useful.

Editorial Department.

Periscope.

A Case of Traumatic Aphasia.*

Dr. B. Bribach reports the following case in the *Archives of Medicine*, December, 1884:

Wilhelmina Müller, a healthy, stout country girl, eight years of age, had her skull fractured on the morning of June 28, by the kick of a mule. She had walked some distance after recovering from a stupor of a few minutes' duration, and I saw her about an hour after the accident happened. She was in a badly frightened and excited condition, but entirely conscious, and walked freely about my office. The fracture was situated in the left temporal region, rather more than two inches long, one-sixth of its extent involving the frontal, the rest the parietal bone. It had the shape of a curve, convex above, as represented in the diagram; the bone below and all along the line was markedly depressed. There was considerable difficulty in disengaging the flap of the cut scalp from between the fractured edges, into which it was firmly wedged, and I did so after giving chloroform. As there were no symptoms of either concussion or compression of the brain evident, I closed the wound by sutures.

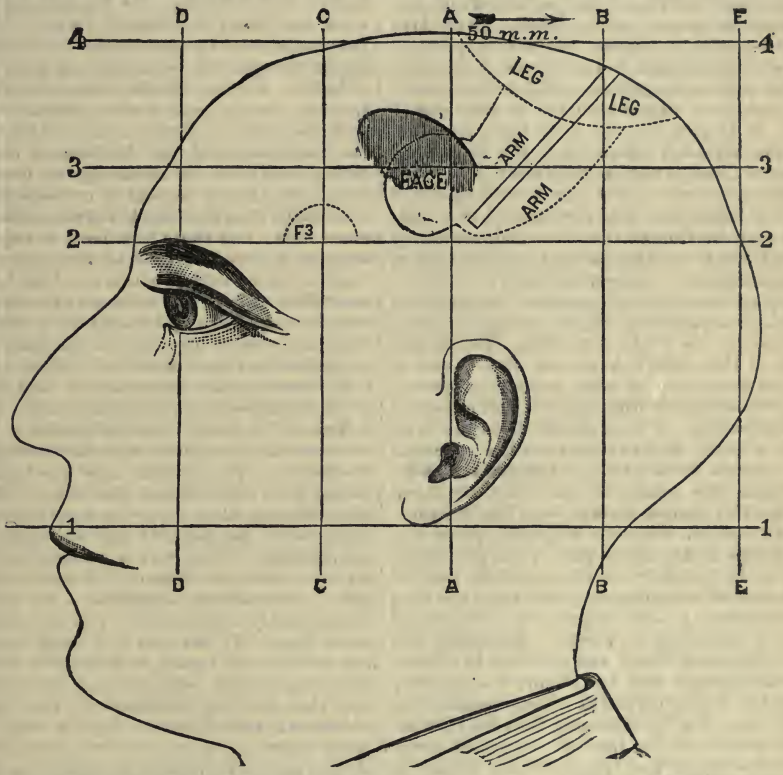
*Dr. Bribach published the substance of this case in the St. Louis *Courier of Medicine* for September, 1884, but the case seems so valuable as to deserve rewriting and illustrating. It may thus secure the full measure of notice it deserves at the hands of neurologists and surgeons.

After the child had recovered from the effects of the anæsthetic, it was found that she lacked the faculty of speech. I ascertained that she had not spoken anything since receiving the injury. A close examination showed absence of paralysis of the muscles of the face, tongue, palate, and limbs. The facial expression was intelligent, and the girl showed evident anxiety to speak, finally making known by signs that she wanted water. Continued efforts to make her speak proved useless, and I directed her father to take her home and keep her quiet, and to induce her to communicate her wants by means of a slate and pencil.

On June 29, twenty-four hours after the accident had occurred, I found the child doing well, excepting the existence of aphasia. Pulse 90, full and moderately strong; temperature normal; coverable anywhere. Patient efforts to make her speak were without result, and I inferred that I had to deal with a case of aphasia produced by pressure on the speech centre. The parents consented to the operation of trephining, which I deemed necessary to relieve the condition and to meet complications by subsequent inflammation. Dr. A. Montgomery, of St. Louis county, who kindly assisted me, concurred in my view of the case, and of the necessity of relieving the compression of the brain.

I trephined the same afternoon, thirty hours after the child was injured, and elevated the entire depressed portion of the skull. The dura mater was not injured, and the inner table of the skull was free from spicula.

June 30. Patient had passed a quiet night, and



I. Lines of Cranio-Cerebral Topography Projected on a Profile of the Head.—1-1. Alveoli-condyloid plane (horizontal); 2-2. Fronto-lamboid line; 4-4. Vertex horizontal. A-A. Auriculo-bregmatic line passing through meatus auditorius, and drawn at right angles to line 1-1; at the top of the skull this line indicates the true bregma. B-B. Vertical drawn parallel to A-A, 50 mm.(2 inches) posterior to it: at its point of impact on the top of the skull this line crosses the posterior end of the fissure of Rolando, the so-called *Rolandic point*. The straight double line extending obliquely from the *Rolandic point* overlies the course of the fissure of Rolando, and is known as the *Rolandic line*. The areas marked off by dotted lines overlie the centres for the leg, arm, face, and for speech (motor function). THE HEAVY CONCAVE LINE WITH SHADING IMPINGING ON THE FACE CENTRE INDICATES THE SITE AND RELATIVE EXTENT OF THE CRANIAL FRACTURE AND DEPRESSION.

appetite and secretions good. She had uttered only one word, "coffee," which she made use of to indicate any of her wants. She had not made use of the slate, but whether from co-existing agraphia, or from lack of training to express her thoughts by means of writing, I was unable to ascertain. No symptoms of paralysis were dis-

taken a hearty breakfast. Pulse and temperature normal. The mother informed me that the girl had slept over eight hours after the operation, and on awaking asked for a drink. In the morning she had again correctly named and asked for some playthings. During my presence the child could not be induced to speak.

July 1. I learned that patient had repeatedly spoken, but seemed to have been confused; she would often call things by wrong names. On removing the dressing, she complained that I hurt her; on this occasion I heard her speak for the first time.

The patient lived four miles from my place; I could see her but once a day, and had no opportunity to closely watch the manner in which the faculty of speech returned. For four or five days there was a certain amount of loss of verbal memory; the speech was rather slow, the articulation perfect, but substitution of wrong names occurred frequently. At the end of ten days, about July 8, she spoke about as well as before.

Surgically, the case progressed very favorably. There was no fever at any time; I allowed the girl to get up at the end of the second week, the scalp-wound being then nearly closed. In the first and second weeks in August, two small splinters of bone were discharged from the wound over the seat of the trephined opening, and I subsequently removed one more, after which the wound closed entirely. It is now covered by a thick cicatrix. The girl has attended school since the beginning of September, and is now as well as ever.

Comparing the seat of the injury with an adult skull, I concluded that the pressure of the fracture had been bearing on the third and ascending frontal and the ascending parietal convolution of the left hemisphere. Subsequent reference to Dr. Seguin's diagrams of cranio-cerebral topography, and exact measurements of the patient's head, showed that in this I was mistaken. The measurements of the child's head are eleven and a half inches from root of nose to occipital protuberance, twelve inches from right to left external meatus auditorius. A line drawn from the true bregma to a point midway between the external angle of the left orbit and the left meatus auditorius crosses the centre of the fracture three and one-quarter inches distant from the bregma. Projections on Dr. Seguin's diagrams place the depressed area on the lower part of the ascending frontal, and but slightly on the posterior part of the third frontal convolution, involving the face centre according to Dr. Seguin, the centre of articulation according to Ferier. Assuming the relative locations of skull and brain to be identical with the patient and Dr. Seguin's diagrams, I can explain the involvement of the speech centre in this case only by assuming that the inferior depressed portion of the fracture exercised some indirect pressure on the speech centre, which is located anterior to the fracture.

Simple Fracture of Skull in Infants followed by Pulsating Tumor.

Before the Pathological Society of London (*Lancet*, January 10, 1885,) Mr. R. J. Godlee read an account of two cases of simple fracture of the skull in infants, followed by the development of a pulsating tumor, and showed some drawings and specimens in illustration. The first case was a female infant, eight months old, that was brought to the hospital the day after a fall of fourteen feet on the side of the head. There had been no unconsciousness or external bleeding at the time; she had vomited shortly after. When seen, there was a large hæmatoma over the right parietal bone, and there was almost complete paralysis on the left side of the body; the reflexes were absent on the left side. There was at at first some difficulty in swallowing. On the fourth day, right-sided convulsions occurred. Next day the paralysis began to improve and the swelling also gradually to disappear. At the end of about a week pulsation was first noticed in the swelling. Three weeks after the injury the hæmatoma was increasing in size and was aspirated, seven and a half ounces of fluid being removed; the fluid was muddy-looking, alkaline, and contained a few corpuscles. In three days another small aspiration was performed, and two days later the swelling was opened, a large quantity of fluid similar to that already obtained came away; likewise some genuine pus. Death occurred next morning. At the autopsy the hæmatoma was found to extend the whole length of the parietal bone. In the middle of it there was a gap in the parietal bone half an inch wide with irregular edges. Brain matter could be seen through the gap, and it was ultimately discovered that there was a direct communication between the hæmatoma and the descending cornu of the lateral ventricle. On removing the bone, the dura mater was found lacerated corresponding to the fracture in the skull, the brain was collapsed on the same side, and there had been a rupture of the temporo-sphenoidal lobe at the upper part that communicated with the interior of the brain as just described. There was extensive meningitis at the base, and arachnitis of the vault on the right side. Mr. Godlee drew attention to the character of the fluid that had been drawn off; there was evidence that it was partly inflammatory and in part derived from the cerebro-spinal fluid. He also referred to the want of correspondence in gravity between the symptoms and the damage done to the brain. The second case was that of a male infant aged five months, that came to the hospital after having fallen on to his head from a height of eight feet. He was cold and collapsed, and had not vomited; there was a hæmatoma extending forwards from the back of the head on the right side. Convulsions appeared a few hours later, being mostly right-sided. The twitchings lasted some days. At the end of a week pulsation was observed in the tumor, and impulse on coughing. The temperature continued at or about normal, but the swelling increased in size, and on the thirteenth and fifteenth days it was aspirated. Very little fluid was, however, drawn off, and the child's general condition remained the same. At the end of two months the child was allowed to be taken home, a shield having been provided to protect the still pulsating swelling. Shortly after this the child was taken to another hospital, where he died in the course of a few days with symptoms of meningitis. On examining the right parietal bone, there was found a large irregular opening, running obliquely downwards and forwards, measuring three inches long by three-quarters of an inch across. At each end of the opening the bone was fissured for nearly an inch. The margins of the opening were very thin, and the absorption of bone seemed to have taken place chiefly at the expense of the outer table. The bone was everywhere very thin, but there were no spots of cranio-tabes. On the other parietal

bone there was an indentation corresponding in shape and size with the above opening; the bone was very thin, quite membraniform, in this region. The symmetry of the lesion of the bone suggested that the child's head might have been squeezed in some way, but there was no history of this. Mr. Godlee pointed out that in the infant the bones of the skull were very flexible, and that they were united by sutures which were soft and permitted of a considerable amount of movement, and further, that the dura mater in young infants was firmly attached to the bones. He thought that these facts would help to explain the different results of direct violence to the skull in the child and in the adult; in the former the force being almost altogether spent upon the part struck.

Pilocarpine in Acute Erysipelas.

Professor Da Costa presented the following case at a recent clinic at the Pennsylvania Hospital (*College and Clinical Record*, January 1, 1885), and made the following remarks:

"I have here a case to show you which I think will interest you, as it brings out rather a novel treatment of erysipelas. I intended to exhibit this to you this morning as a case of erysipelas, but I find that the erysipelas is gone. I, therefore, can only speak of the treatment, which has proved more quickly efficacious than I supposed it would.

"This man, B. K., 32 years of age, a fireman, was admitted only day before yesterday. This is the record upon admission: 'He says that he was quite well yesterday (November 12), but did not go to work, as he was celebrating the election. In the evening, according to his statement, he was not drunk, though he had been drinking a little, and became engaged in a very earnest political discussion, when some one equally earnest struck him in the right eye, making a bruise on the cheek and a small lacerated wound of the eyebrow,' the evidence of which you see for yourselves. The man at that time was quite well, although under the influence of liquor. 'During the night he had much pain in his eye, and in the morning the eyelids were œdematous, and the cheek likewise swollen, red, and burning.' When he applied for admission the inflammation was confined to the right side of the face, but it spread rapidly, and the same afternoon both eyes were closed. It is worth adding to this history that he had slept out all Wednesday night after receiving the injury. He was admitted on Thursday morning, with erysipelas of the upper part of the face, which was rapidly spreading over the brow. His pulse was 80; temperature, 102.8°; respiration, 22. The urine was examined, with a negative result. He was ordered tincture of the chloride of iron, twenty drops every three hours, but only received one dose; as the disease was rapidly spreading, and something was needed to make a prompt impression, I used another and more active agent. This was not the first case in which I had used this remedy, but it was the first in which I obtained such relief. He received, hypodermically, one-sixth of a grain of the muriate of pilocarpine. The result was remarkable. Here is the temperature record: the temperature fell from 102° to 99½°. He sweat profusely for an hour and a half, and there was no further development of the erysipelas; not only did it not spread further, but what did exist quickly subsided. No local treatment was employed, not even cold applications; therefore, whatever success was obtained was from the pilocarpine.

"I call your attention to this treatment of erysipelas. I said that it had not been my first case, although it was the most striking case I have seen. As long as five years ago I used jaborandi in the treatment of erysipelas until sweating was produced, and, I thought, with the result of checking further development. In one case with high temperature the disease had already made some headway, and did not subside so quickly. Under the use of iron the disease had not been controlled, but the fluid extract of jaborandi, given every two hours, checked it. I have since used the jaborandi in connection with the iron at times with good results. This is, therefore, not a new treatment with me, as I have used it for some time. Jaborandi and pilocarpine, its active principle, are, of course, similar in their effects.

"I have called your attention to this treatment, not because I believe it will be followed by the same result in every case, but because it is worthy of a trial. If you get a case of erysipelas in its beginning, use pilocarpine. It has saved this man a long and dangerous illness; and, as he had been drinking, as he says he had, the results might have been serious. In the use of this treatment it should be borne in mind that, in order to be fully effective, profuse sweating must be produced.

Psychical Troubles Among Children.

In the *Semaine Med.*, July, 1884, Dr. Leidisdorf says: "Fifty years ago it was absolutely denied that psychical troubles existed among children. It is only within the past ten years that the subject has been discussed by alienists to any extent. During a given three years, 1,714 insane patients were received at the hospital at Döbling (Vienna), who were over eighteen years of age, while only seventeen under the age of eighteen were received. By the last census of Berlin, it appears that there is in that city one insane adult to 400 sane ones, while of children the proportion is one to 1,400; but the author thinks that no conclusion can be drawn from these statistics. As the result of the author's minute observation, the opinion is advanced that there are few permanent psychical troubles among children, though transitory ones are abundant. Of the latter, the author has observed among children four or five years of age sudden attacks of depression, melancholy, or bad humor. He mentions the case of an intelligent little girl who was suddenly seized with fear that she should lose her parents and be abandoned by everybody, and who became profoundly depressed as a consequence. The same condition is sometimes produced by exaggerated concern on the part of friends for the health of a child, and again by the sight of dead or sick people. Hallucinations are common enough in the psychical life of children, a familiar example being the *night terrors* to which many children are subject. Somnambulism is also of not infrequent occurrence, a condition resembling this sometimes occurring also by

day and while the child is awake. An interesting case of the latter variety occurred in the author's experience. Another class of psychical troubles may be permanent. [These are called by the author *zwangsvorstellungen*, a word which has no exact English equivalent; the corresponding French term is *imaginations forcées.*] Such a condition occurs when, for example, a child is filled with fear at the sight of a needle; or, when such a question is asked as, What is the world? and this tendency to mental perturbation may last during life. Permanent psychical troubles are rarely seen in children who are under fourteen years of age. Among the neuroses which are most likely to lead to permanent psychical troubles, are mentioned chorea, epilepsy, and hysteria; and meningitis is less frequently a predisposing cause. One case is reported by the author of progressive paralysis of the insane in a girl fifteen years of age. This is a most unusual condition, only one other case being recorded in medical literature."

The Importance of Oxygen and and Ozone as Therapeutic Agents.

The *National Druggist* tells us that in the *Archiven für die Gesammte Physiologie*, M. Filipow contributes a study on this subject, of which the following is an extract:

At the request of Professor Dogiel, of Kasan, the author carried out a series of experiments on mammalia (including man) and fishes, with the view of reconciling, if possible, the numerous and contradictory results hitherto obtained as to the influence of oxygen on the animal organism.

After two pupils of Dogiel had arrived at the conclusion that neither the pulse nor the temperature were in the least affected by the inhalation of pure oxygen, it was demonstrated (in 1880) that the contrary was true, and that both were augmented very considerably. It was further shown that oxygen, breathed instead of atmospheric air, arouses the appetite, and thus increases the weight of the body; that it creates a slight nausea, and increases the number of the red blood corpuscles. The number of the white corpuscles, and the quantity and the relative composition of the urine, remained unaltered. Ozone, in addition to these effects, induces sleep in man and lower animals, and passes (as ozone) into the blood. The experiments with oxygen, when carried out on human beings, were performed by means of an apparatus which carried off the expired gases without allowing them to come in contact or mingle with the inspired oxygen. Frogs were simply placed under a bell glass, which was connected with a gasometer, and was placed over water. The conclusions reached by Filipow concerning oxygen were that the inhalation of pure oxygen has no advantages over that of pure atmospheric air, at least so far as heart action, breathing, and bodily temperature are concerned. In poisoning by chloroform, ethylic alcohol, sulphuretted hydrogen, and carbonic oxide, the inhalation of oxygen has no advantage whatever over that of ordinary air.

The inhalation of diluted ozone produced a feeling of warmth in the chest, a slight stupefaction, sleepiness, and a slight coughing. Breathed in its concentrated state, on the contrary, it produced excitement and aroused the energies. There was no tendency to sleep. The conclusions of Filipow on this head were, therefore, that the inhalation of diluted ozone can not, as stated by Binz, be used as a means of producing sleep. The inhalation of pure or concentrated ozone causes a powerful excitement of the mucous membrane, and is therefore injurious to man and animals—a conclusion which agrees with those reached by earlier experimenters. The taking up of ozone and blood through the organs of respiration must, as heretofore, be regarded as not demonstrated.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A careful report on tinnitus aurium by Dr. G. C. Catlett, of St. Joseph, Mo., reprinted from the *American Journal of Insanity*, makes a pamphlet of twenty pages of well-digested matter.

——In a brochure of twenty pages, published by George S. Davis, Detroit, Dr. Robert M. Smith describes the most recent methods of studying the physiological action of drugs. As these methods are, many of them, of recent introduction, and differ materially from those in vogue ten years ago, the suggestions are timely.

BOOK NOTICES.

Denison's Climatic Maps of the United States. Published by Rand, McNally & Co., Chicago, Ill. Prepared by Charles Denison, M. D., of Denver, Colorado.

This publication is a well-printed and colored wall-map, showing the temperature, humidity, elevation, rainfall, prevailing winds, and other climatic features of the United States and territories. It is especially prepared with reference to the wants of physicians and health-seekers, and to show the sanitary characteristics of localities.

The climates are presented according to the seasons—spring, summer, autumn, and winter—and the statistics have been carefully reduced from the observations of the Signal Service Bureau, and may, therefore, be assumed as entirely accurate.

These maps are mounted in various ways and the information they contain, while interesting to all, is especially instructive to physicians, who, by their use, can intelligently select and recommend a climate to suit the requirements of any particular case for which a change is desired. We can recommend them as the most satisfactory of the kind that have ever been published. They may be had of the publishers, who will send prices, etc., on application.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address
DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE CHOLERA EPIDEMIC IN PARIS.

Dr. Dujardin-Beaumetz communicated to the French Academy of Medicine at its December meeting some interesting data concerning the recent epidemic of Asiatic cholera in Paris (*Deutsche Medizinal Zeitung*, p. 607, 1884).

The first case appeared during the night from the 3d to the 4th of November, in Aubervilliers, the last happening at this place on the 15th of the same month.

November 5, at a time when the general condition of the city was one of remarkably good health, there were already reported in Paris, at several places simultaneously, some ten or fifteen cases. The epidemic rapidly increased up to the 10th, on which day it reached its height, and then slowly decreased, until at the date of the report about one fatal case occurred daily.

Comparing the mortality of this epidemic, viz., 4.05 deaths for each 10,000 inhabitants (the absolute number of deaths being 912, of whom 382 were women and 530 men), with that of former epidemics of the same disease, the following result is obtained:

1832, of 10,000 inhabitants, 234.16 died.
1849, of 10,000 inhabitants, 185.31 died.
1854, of 10,000 inhabitants, 78.0 died.
1873, of 10,000 inhabitants, 4.6 died.
1884, of 10,000 inhabitants, 4.05 died.

This proves the gradual, but certain decrease in the severity of the epidemic.

The different sections of the city suffered in so changing a manner, that no deductions can be made from the statistics referring to them.

In Toulon last year 669 persons died of cholera, viz., 12.6 of each 1,000 inhabitants; but considering the great number of individuals that left the city or suffered from the disease somewhere else, the mortality-rate has in fact been a much higher one. The same may be said of Marseilles, where 49.4 per cent. died of each 10,000.

Regarding the origin of last year's epidemic in Paris, it is not possible even to guess. Certain it is, that weak and sickly persons, as also specially "topers," contributed by far the greatest majority of deaths. An attempt to connect the march

and spread of the disease with the distribution of the water had to be given up. As well known, two aqueducts run parallel in the streets of Paris, one carrying the water from the Seine and the Ourcq, the other from the Vanne and Dhuys. To determine the mooted question, it would have been necessary to inquire in every house, from which line the water consumed had been procured; and even then the result would not have been deciding, as both lines so intimately anastomose with each other that it is an impossibility in most houses to say from which line the water had been obtained. But the information has been nevertheless gained, that the districts provided with water from the Ourcq suffered most severely, or rather, that in the sections most affected this water was the one by far mostly used.

Of special salutary effect seem to have been the police measures for the transport and the disinfection of the sick and their residences. From November 4th to 30th there were thirty wagons which specially served the purpose of transporting more than 900 patients to the hospital, and 73 "désinfecteurs," divided into groups, and having at their disposition thirty-nine wagons, carried out more than 795 disinfections. To these figures must be added those obtained from every "mayoralty" of the city; those above-mentioned having been under supervision of the central police, while each district had besides its own transport wagons and its own disinfectives.

That these measures have had a great influence upon the severity of the epidemic, and decidedly contributed a great deal in diminishing the activity of the disease, becomes clear, if we remember that the epidemic first began with the same severity that former ones had shown, and that was noticed in Toulon, Marseilles, and at other places; and we must also not forget that the only difference between this and other epidemics consists in the number of persons who, during the same length of time, were victims of the disease. Comparing the number of individuals that were admitted to the cholera hospitals of Paris during each epidemic with the number of deaths, it will be found that the difference is a very small one.

There were admitted into the hospitals in
Toulon, 221 persons, of whom 55.6 died.
Marseilles, 659 persons, of whom 51.1 died.
Paris, 1,037 persons, of whom 54.49 died.
Nantes, —— persons, of whom 51.— died.

After the reading of the report, a debate took place, during which Dr. Hardy expressed the opinion that the simultaneous appearance of the disease in different parts of the city, and at a time when the general hygienic conditions were excellent, decidedly proved that the drinking water had nothing to do with the spread of cholera. He also praised the measures taken by the city government, but thought that the next time they should be introduced and executed with less noise and talk, as these but disquieted the inhabitants and created fear. It would further be better to omit the forced fumigations in the rooms of cholera patients, as they were directed against an unknown agent.

Dr. Dujardin-Beaumetz defended the fumigations, which had been instituted in analogy with those long since practiced with such great success by the military authorities in the case of typhus, small-pox, etc. There was certain proof that some house epidemics had been prevented, and others extinguished, by these fumigations.

In general these data do not contain much that is new; still they are of great interest, first as proving the diminution in the severity of the disease in consequence of the better hygienic conditions and the greater knowledge we possess of the malady; and secondly, as indicating to us some of the measures which, as the transport and the systematic disinfection, seem to have been specially successful in the prevention of the spread of the epidemic.

REFINEMENTS OF DIAGNOSIS.

We have no disposition to quarrel with specialists; to a certain extent, that is to say within a healthy professional limit, we are advocates of specialism. As we have already had occasion to say, the progress of medical science during the

last ten or fifteen years has been too great for any one mind to grasp in its entirety. There are so many workers, so many investigators, who are constantly adding to our sum of knowledge, that it would be utterly impossible for any one man to read, much less *remember*, all even that is worthy of remembrance. But—and this is a big BUT—we feel compelled to ask the question, as we have done before, whether specialism is not running wild.

An observant physician who goes about among his fellows, who visits hospitals and medical societies, is continually hearing some *honest* man admit that his autopsy has proven the falsity of his diagnosis, even in some ordinary disease that is usually supposed to have good and well-established rules for its recognition. How then do we feel when we read of such a wonderfully accurate diagnosis as "*Catarrhal Fallopian Tubes.*"

We are not specialists, and we feel that we may be accused of great ignorance in not knowing how to recognize "Catarrhal Fallopian Tubes," but at the same time we are quite sure that the older men in the profession—those men who are *solid*, so to speak, those men who have battled the storm, and whose mature minds view things as they really are and should be, and not through the biased vision of a modern city specialist—will agree with us that when a man says that he has been able to diagnose "*Catarrhal Fallopian Tubes*" before operation, he is at least open to the suspicion of "*guessing for effect*," and that if results verify his sensational diagnosis, he may be called a "lucky man" in truth. We will not mention names, but such are the facts as stated in a recent issue of one of our most reputable medical journals. The author of the article says—we give his own words:

"By a careful study of each case and by the use of preparatory treatment to soften and relax the adhesions, I was able, in almost every case, to make a more or less exact diagnosis before operating."

"Eight were cases of pyo-salpinx; two hydro-salpinx; and four *catarrhal tubes* with peritoneal adhesions."

Of course, we can all readily conceive that catarrh of the fallopian tubes may exist; it is most probable that such a condition does exist in a large majority of the cases of sterility that come under our observation; and our only wonder is that all of our *fashionable* city women are not troubled with it—perhaps they are: but for a man to claim that he can diagnose a catarrhal condition of a little tube absolutely hidden from his sight, is, to say the least, a very great claim. Of course, our author does not claim that he can always diagnose this condition; but the extracts which we have given from his paper show that he desires to convey the impression that he possesses very peculiar powers of diagnosis, which would make him a very desirable person for country doctors to send their puzzling cases to.

We do not wish to reflect personally on any one, or to decry true specialism; but we desire to take this opportunity to annonnce our belief that specialism is being carried to a ridiculous extent. It is time for us to tell the *intelligent* country doctor that he is just as capable of treating the majority of cases that come before him as is the fashionable city specialist.

If the *country doctor* (who is usually considered to be a second-rate man, just because he lives in the country) keeps himself abreast of the times by active reading, he is perfectly capable of attending to all the cases (*almost*) that come to him. Of course there are certain legitimate specialties, as the *eye* and *ear*, with which the general practitioner has not the opportunities to familiarize himself; although even here, by careful and thorough study, he can equip himself very thoroughly, yet we would advise that such cases be sent to well-known specialists. But when it comes to surgical cases, we cannot see why an intelligent, well-read country doctor cannot make himself as competent as any city doctor.

Of course, mechanical skill is a very important point; but one must remember that our large cities are now so crowded with specialists in their various branches, and the majority of them comparatively young men, that their opportunities for acquiring adeptness in mechanical skill are comparatively limited. We must again say, that we are in favor of *legitimate specialism*, but that

when we read of these beautiful niceties in diagnosis, we are constrained to ask the older members of our profession whether human nature is really any better off to-day than it was in the days of Chapman, Dewees, Physick, or Jackson, and whether our refinements of diagnosis among our fashionable specialists do not rather tend to multiply the ills of humanity, and to suggest new diseases to their patients, than to add to the real practical progress of our profession.

Our large cities are gradually filling up with specialists, and it is a necessity. Trade is not conducted as it was in times gone by. Each successful business house to-day has built up its success on some special article for which it has secured a reputation; so it is with physicians, and so it must be, since such is the order of the day; but, do not let us go too far. Let us give all credit to legitimate specialism, but let us look with a certain amount of distrust upon these refinements of diagnosis.

Notes and Comments.

Total Obliteration of Urethral Canal in a New-Born Child; Operation; Recovery.

Dr. Edward Wood Forster reports the following case in the *Brit. Med. Jour.*, January 3, 1885:

On January 3, 1880, Mrs. J. was confined at full term of a handsome and fully-developed boy. A slight venous congestion marked the site of the urethral orifice, on the under side of which there was a shallow groove of about the one-sixth of an inch in length, not, however, dipping into the urethral site, nor taking from its normal length, but infringing slightly upon the frænum. The prepuce was retracted. The examination evidenced occlusion, and the symptoms called for prompt action.

At 7:30 p. m., the infant was placed under chloroform by Dr. Fothergill, who ably controlled the anæsthetization thoughout.

The operation consisted in a gentle, but firm, screwing and pushing movement through the occluding material, and it proved that the canal was obliterated in its entire length. When approaching the neck of the bladder, the index finger of my left hand was passed into the rectum, and retained there, as indicator and gubernator, until the catheter had passed through the membranous and prostatic portions, and had freely entered the bladder. Very little blood was lost. The instruments used were a probe, director, a stout curved stilette, and a small-sized catheter belonging to a pocket-case. The stilette required very delicate management, but proved an apt instrument. The break into the bladder was affected by the catheter, and water immediately flowed. An oiled bougie was passed for two or three days; the wound healed rapidly, and, strange to say, the infant never showed signs of any suffering from the flow of urine over the abraded surface. At the end of a week or ten days the cure was complete, and remained so.

This case is interesting because of its rarity. Sir Henry Thompson, in his article on "Diseases of the Urinary Organs," in Holmes' *System of Surgery*, says, "The canal is sometimes occluded, and this produces retention of urine and death during the early hours of life."

We may possibly conjecture that, in this case, the developmental process had been somewhat checked, the "uro-genital sinus" retaining something of its original character. The very slight hypospadias would give force to the supposition.

A Point in the Treatment of Purulent Ophthalmia.

Dr. Edgar A. Browne (*Brit. Med. Jour.*, January 10, 1885,) considers that the two most important considerations in the treatment of this disease are to wash away the infective material as thoroughly and as early as possible, and to render the conjunctival epithelium and secretions as nearly as may be aseptic. For the first indication he has devised an instrument that enables him to throw a stream of pure or medicated water into the upper sulcus for any length of time he pleases.

The instrument resembles an ordinary lid-elevator, but it is rather deeper in the claw, and constructed of hollow-plated tubing, instead of wire. It is furnished above with a handle, and behind a small curved nozzle is connected by means of an India-rubber pipe, six or seven feet long, with a resorvoir capable of containing about a quart of solution. The limb that passes beneath the upper eyelid is pierced with six fine holes, through which the fluid issues as a douche. A stop-cock or spring-clip is provided to regulate the flow.

In use, the reservoir is filled and hung up. The surgeon or attendant stands behind the patient, who holds his head slightly inclined over a basin. The elevator is gently insinuated under the upper lid, and the stream turned on.

The points requiring attention are these:

1. It is necessary to ascertain that the orifices are patent; they are liable to become clogged; four in full play are sufficient.

2. The reservoir must be well elevated to give a good fall, and it must be nearly full to give a good pressure.

Dr. B. had very good results from a solution of trichlorphenol. He finds a two per cent. solution amply strong for the first applications in gonorrhœal ophthalmia, and one per cent. for ordinary use. It gives rise to a good deal of smarting, which ceases directly the flow is stopped. Some skins are easily irritated by its flow over the cheek; the majority are not affected. The skin may be protected by vaseline if necessary. He uses it twice a day for about a quarter of an hour. In one severe case he used it three times a day. As the case progresses, a one per cent. solution is sufficient; in some, a half per cent.

Lung Disease in a Lion.

Before the Academy of Medicine in Ireland (*Brit. Med. Jour.*, January 3, 1885):

Mr. Abraham exhibited the left lung of a lion which had been born in the zoölogical gardens, had lived there twelve years, and recently died. The animal had had good health till October first, when there was sudden cold weather. The lion refused food, seemed feverish and thirsty, and his respiration became exceedingly rapid. He appeared to have pleurisy, his chest being fixed, and his breathing abdominal. An attempt to administer medicine failed. He took little food, except occasionally. He drank some nitre in water, with diuretic effect. He had no cough, but two or three times he spat mucus, which toward the end became bloody. Ultimately, he became emaciated, and died. His viscera were healthy, except the lungs. There was no pleurisy, but the lungs were diseased, mottled in appearance, and hard and lumpy to the touch. On section, they presented a curious honeycombed aspect. The bronchial tubes were enormously enlarged. In the lower lobe of the left lung was a large cavity. The microscopic sections of various parts of the lung did not show the structure of tubercle, nor did any of the bronchial glands. He was not sure what the disease was. The father of the lion died in precisely the same way.

Mr. Baker remarked that lung disease was common among cats, which frequently suffered like the lion in question.

The President observed that monkeys were subject to consumption. In the lion's lungs exhibited, he had no doubt the cavity existed for years, and a small amount of cold sufficed to kill one of the large carnivora.

Mr. Abraham said that, long ago, Dr. Haughton discovered that tubercular phthisis was not so common in monkeys as was generally thought, and he showed it in a paper read many years ago before the old Pathological Society. And in a paper read before the Zoölogical Garden of London, Mr. Sutton recently came to the same conclusion.

Splenic Anæmia Treated by Phosphorus.

In the *Brit. Med. Jour.*, January 3, 1885, Mr. T. Jenner Verrall reports this case:

The patient, a rickety child, aged fourteen months, was first seen in the middle of October, 1883. The spleen occupied the whole of the left side of the abdomen, extending forwards nearly to the umbilicus and backwards to the spine. The blood examined was very pale; about thirty white corpuscles could be counted in the microscopic field. Under Parrish's food and cod-liver oil, the child grew worse, losing flesh rapidly. At the end of a month Parrish's food was discontinued, and to the teaspoonful of oil was added a minim of the oleum phosphoratum of the *British Pharmacopœia*, twice a day. From this time the child improved. The diet ordinarily given to children of this age was not allowed, except that the juice of an ounce of raw beef was given daily for about five weeks; but even this small change was not made until the phosphorus had been taken for a fortnight, and had already produced an effect. The spleen diminished in size and hardness, till, on March 12, 1884, when the phosphorus was given up, it measured about four inches in length and depth, and was soft and movable. Very few white cells could be seen; and the blood was much darker. The improvement was permanent, the child being under observation for six months longer, growing and gaining flesh. Mr. Verrall pointed out that this case was an exception to the rule laid down by Sir W. Jenner, that enlargement of the spleen in rickets was always due to albuminoid infiltration, and was unaccompanied by any increased number of white cells. He believed that the evil lay in deficiency of nerve-power, for which the phosphorus would be an appropriate remedy. He attached great importance to the smallness of the dose, and to the length of time over which the treatment extended.

The Treatment of Psoriasis.

This obstinate disease, with its great tendency

to recur is the bete noir of the physician, hence it is well that we should be familiar with a number of methods of treatment, that we may turn from one to another until successful. We therefore note from the *Chicago Med. Jour.* (January, 1885), the following treatment as recommended by Dr. Henry J. Reynolds:

"We will first, for the purpose of getting rid of the scales, apply carbolized ointment twice a day for two days, then the entire body will be bathed in hot water with plenty of soap and friction. The same ointment will again be applied for two or more days, and followed by the same bathing process. We will then have a chrysarobin ointment, of grs. xx. to ung. aquæ rosæ ℥j., applied twice a day to every individual lesion on the body. The chrysarobin should be suspended and the former process substituted about every week or ten days. Arsenic may also be given internally in this disease, beginning with about five drops of Fowler's solution, three times a day, and gradually increasing, as indicated by the effects.

For the prevention of the return of the disease frequent bathing with hot water and green soap, and measures which tend to keep the skin active, are indicated.

A Remedy for Street Noises.

For those who, on account of nervousness, are morbidly sensitive to noises, the following ingenious, but simple, device, which a physician recommends in the *London Med. Times*, may prove of value. He thus describes it:

"I placed some spermaceti ointment in the centre of a little square of thin limp cotton, brought the corners together, tied them with thread, and inserted one of the little plugs well into each ear, and found—after a little kneading and gentle pressure—that I was absolutely deaf to all ordinary sounds, such as the loud barking of dogs, and the rumbling of heavy carriages in the streets.

"A couple of points must be carefully attended to. The ointment must not be too soft, the quantity about the size of a small pea, and the little bag must be somewhat larger than its contents, to allow the plug to take the shape of the auditory canal. If the bag be too small, or its contents too large, it cannot be inserted into the ear; and if applied only to the orifice, it entirely fails in its object. This little experiment is easily tried, and a daily experience of over twelve months, warrants me in saying that it will be found invaluable in the sick room."

Nursing by the Mother.

While nearly all physicians agree that maternal nursing is much to be preferred to any form of artificial feeding, yet it sometimes happens that the mother either really is, or makes it seem that she is, unable to suckle her child owing to a want of a sufficient supply of milk. This drawback, which will prove a serious one to the child, may be overcome in many cases; for as Dr. Jerome Walker tells us in the *Archives of Pediatrics*, January 15, 1885, if there is a judicious following out of hygienic measures, especially those relating to food, out-door exercise, and the fit of clothing, and if there is a judicious use of medication, such as will increase muscular strength, produce or maintain a healthy appetite, rouse the spirits, and provide for free elimination of waste products, then a healthy secretion of milk is made possible, even in some of the most obdurate instances of defective lactation, and our patients gain in many ways by our encouragement of nursing by the mother. We cannot believe at present that the dietetics of infancy are so well understood that artificial feeding of young babies should largely take the place of maternal nursing.

Portion of Ear of Corn Penetrating the Larynx.

Before the Manchester Medical Society, December 3, 1884, Dr. Hodgkinson gave an account of the following case: John N., aged 23, applied at the Throat Hospital, complaining of pain in the throat, increased in swallowing, together with hoarseness, slight difficulty of breathing, and cough. He stated that four days previously, whilst laughing with a piece of straw in his mouth, it slipped down his throat. He was first seen by Dr. Gamgee, who noticed a swollen condition of the higher ary-epiglottic fold, which was surmounted by a grey slough. Dr. Hodgkinson afterwards saw the case; and, the slough having cleared away, he recognized about an eighth of an inch of straw projecting from the œdematous ary-epiglottic fold. This was removed with laryngeal forceps. It was part of an ear of corn, which had been embedded in the tissue to the extent of three-quarters of an inch. All symptoms disappeared on removal; the opening in the ary-epiglottic fold remaining for several days.

Intussusception.

This affection is sufficiently rare to warrant the occasional publication of cases in order that its possibility may be kept prominently before our minds. Dr. D. Jamison reports the following case

in the *New Orleans Med. and Surg. Jour.*, January, 1885:

Joe Cooper, colored, aged thirty-one years, was admitted September 29, into ward No. 33. He appeared to be suffering from constipation, with some abdominal tenderness on pressure. Before he came to the hospital the pain was so great that he fell down in the street and had to be brought to the hospital in a wagon. He was given calomel and soda, large injections, and sulph. mor. (hypodermatically). For two days he seemed to be better, although he had not a satisfactory operation. October 2, he complained of great pain; Ol. Tig. and Ol. Ric., with morphine, were at once given. In two hours he vomited stercoraceous matter and immediately became very much worse. His condition is now so grave that an operation is judged useless. He died in a few hours. The post mortem confirmed the diagnosis. The portion of the intestine involved was the ileum, over three inches were invaginated, the upper gut slipping into the lower. There was extensive peritonitis.

Cancer of the Peritoneum.

Dr. Samuel Fenwick has been recently delivering a course of lectures on "Cases of Difficult Diagnosis," which are being published in the *Lancet*. Speaking of *stricture of the intestines*, he says:

"Cancer of the peritoneum frequently gives rise to constriction and obstruction of the intestines. When the disease is, as is usually the case, associated with ascites and with abdominal tumors, the diagnosis is tolerably easy. But there is another and more rare case, in which the cancer is scattered over the peritoneum in a miliary form, and in which attacks of colic are for some time the only prominent symptom; and here it would be a matter of great difficulty to arrive at a correct diagnosis in an early stage of the disease. You should in such instances always examine by the rectum, for often small tumors are to be felt in Douglas's pouch, when they are nowhere else to be discovered; and if in addition to the presence of a tumor you find a gradual loss of flesh and strength, the occurrence of ascites, or an implication of some other organ, you have facts that will enable you to arrive at a correct conclusion."

Religious Influence in the Treatment of Inebriety.

Opinion will probably always be divided upon the question as to whether inebriety is a vice or a disease. There are a great many eminent men who hold the latter view, and prominently among them is Dr. T. D. Crothers, the able Superintendent of Walnut Lodge, Hartford, Conn. We have already published several papers from this gentleman, in which he strongly advocates the disease view, and wherein he offers very good arguments to sustain his position. We now note his conclusions of a paper in the *Quarterly Journal of Inebriety* for January, 1885, as follows:

1. Inebriety is a physical disease which must be reached by both physical and psychical means.

2. All methods of treatment must be along the line of natural laws, and include all means, both physical and spiritual, that can build up and strengthen the entire man.

3. Spiritual means are only valuable in proportion as they are used with other means, and where they are effectual alone, they are the exception to the rule and cannot indicate any direct line of treatment.

Some Good Formulæ.

For the following we are indebted to the *College and Clinical Record*, January 1, 1885:

As a stimulating application to a chancroid, Prof. Gross recommends:

℞.	Acid tannici,	gr. ij.	
	Ung. hydrarg. nit.,	ʒj.	
	Adipis benzoat.,	ʒj.	M.

Sig.—Apply on a a piece of lint.

For the sweating of phthisis, Prof. Bartholow advises:

℞.	Acid. gallici,	ʒss.	
	Ext. belladonnæ,	gr. ij.	M.

Ft. pil. x.

Sig.—Two pills at bedtime.

A favorite prescription of Prof. Da Costa in marked idiopathic anæmia is:

℞.	Ferri sulph.,	ʒj.	
	Potassii carb.,	ʒj.	M.

Ft. pil. No. xl.

Sig.—One after meals for first week; increase dose in second week, etc.

If the patient is a female, suspend treatment during menstruation.

—Before the Brighton and Sussex Medico-Chirurgical Society (December 4, 1884), Dr. Ross showed a gall-stone, weighing upwards of four drachms, passed at stool by a man aged 50. He had suffered from frequent bilious attacks and from jaundice during the last year, and had the aspect of malignant disease. On October 16, vomiting, hæmatemesis, obstruction, tympanites, and pain, referred mostly to the ileo-cæcal region, set in. On October 22d, when apparently dying, he felt a sudden burst and escape of wind. The stone was then evacuated by the bowel, and he rapidly recovered.

CORRESPONDENCE.

Providence Letter.

EDS. MED. AND SURG. REPORTER:—

The people of our city have recently been treated to a rich dish in the form of a trial for procuring criminal abortion, the result of which was a disagreement of the jury. Scarcely had this trial reached its end, when another case was reported. If there are still more to follow, and all are to escape punishment, it will not be long ere Rhode Island shall have the honor of sheltering an abortion mania, as it now does the divorce mania. The fact is, our laws are very lax upon both of these important subjects.

The following from the Attorney General's plea is so full of sound sense, that I am going to give it verbatim: "One verdict against this thing, against this evil and this crime, will save more lives than when twenty verdicts of murder have been found."

The last quarterly meeting of the State Society was one of much interest. Two very good papers were read, and though treating of rather trite subjects, yet were presented in such an attractive form as to claim attention. "The Nature and Prevention of Puerperal Fever" was well treated by Dr. Fuller. He placed it among the septic diseases, though claiming that the definition should be broad enough to include blood-poisoning from infection, be the cause septic or zymotic. His treatment was that advocated by the modern authorities.

In the discussion which followed, several members took part.

Dr. Terry said that if we did not recognize the germ theory, the statistics showed the result of treatment based upon this theory to be a vast improvement upon the result of treatment based on any other theory, hence we should consider and treat it as germ disease. He claimed that the rigid rules now advocated so strongly by Dr. Thomas, of New York, were in force in the Boston Lying-In Hospital as early as 1876, and that Dr. Thomas did not introduce them, but did bring them permanently before the profession.

Dr. Newhall claimed that they were introduced by Dr. Thomas, but offered no facts to support his statement. Dr. Newhall opposed all theories and treatments relating to germs. Seeing alone was believing.

Dr. Ballou opposed all meddlesome attentions. In his experience and opinion, nature was more to be depended upon than injections and the many other things now advocated.

Dr. Caswell supported the happy medium, though when the fever was epidemic stronger measures would be required.

Dr. Ely said, as parturition is a physiological process, it requires no set rules in treatment. He considered of great importance absolute cleanliness, and for this purpose antiseptic solutions were not called for; indeed, he had very little faith in them, the principal virtue being in the pure water contained. He doubted the advisability of intra-uterine injections in any case.

The other paper was concerned mainly in giving statistics, of which some very interesting ones were read. It was a report of the "Investigation of the Premises and Dwellings of Three Hundred Cases of Typhoid Fever." These cases occurred in Providence during the epidemic of '82 and '83. The report was very thorough, and covered nearly every subject, such as age, occupation, water supply, heating etc. It was a very instructive paper in a sanitary point of view.

"Providence Lying-in Hospital. Incorporated, February 29, 1884." Such is the title of a little pamphlet handed to the members as the Society adjourned. It is neatly gotten up, and sets forth by whom and for what this hospital is designed. It also contains a list of officers; the act of incorporation; constitution and by-laws. It will be seen that this project is dated 1884. Yet nearly a year has elapsed since full power was granted, and there seem to be no indications of progress.

In looking for a reason, one is obliged to be satisfied with his own, as none is furnished by those who have the enterprise in hand. It can't be for want of funds, or if this be the cause, it can't stand, for a well-known party of this city has agreed to furnish the hospital in all its parts. The demand for such an institution is recognized by all. And no doubt it can be made to do a good work. It has been no uncommon occurrence for several patients of Providence to be registered at the Boston Lying-in Hospital during a year, though a majority gave their residence as Boston, thus obtaining attention at a reduced fee. It may be that a little jealousy has been sifted into the thing, for it is pretty well understood that the Rhode Island Hospital does not favor it. Possibly this is from a fear that some of the favors it now enjoys may be turned into another channel.

In speaking of the Rhode Island Hospital, I am reminded of the fact that a cottage was commenced there in the fall. It was to furnish a place for gynæcological operations. Its progress has been slow, indeed, and time alone can tell when it will be completed. In the meantime, the patient with the large ovarian tumor is daily growing weaker. Its early completion was urged in a great measure for her benefit; and had it been completed in the time named, there is every reason to think a favorable prognosis could have been given.

The Providence Medical Association is composed of those members of the Rhode Island Medical Society who reside in Providence. They meet on the first Monday evening of every month to report cases and discuss other matters of interest.

At a recent meeting, a member in speaking of post-partum hemorrhage, spoke very highly of alum, saying that he used it in preference to anything else. His mode of using was to take a piece weighing three or four ounces and pass it well up into the vagina. At the last meeting the subject of perineal section was well discussed and some very interesting cases reported—one of eighteen sinuses, from which urine passed, was permanently relieved—the mode of operating being to plunge the knife directly into the bladder through the median line; dissecting the parts and cutting slowly being objected to as it was impossible to distinguish one part from another.

The State Society has a fine library, and now has started the nucleus for a museum. At the last meeting a Museum Committee was appointed,

with Dr. McCaw as chairman. He is deeply interested in pathology, and has performed a large number of autopsies during the last two years. Postal cards have been sent to all Fellows of the Rhode Island Medical Society, requesting them to send in such specimens as they have and others which they may obtain.

At the last meeting of the State Society a rare case was reported by Dr. Dyer—it being a *fistula of the antritragus* Offensive matter was being constantly discharged. After going the usual rounds and having had various solutions injected into it, the case fell into the hands of Dr. Dyer. He passed a piece of platinum wire down to the bottom of the sac, and by means of a curved needle it was passed through the wall of the sac. The wire was then connected with a battery, and after coming to a white heat, the wire was disconnected from the battery and withdrawn. The result was complete obliteration of the sac. At the same meeting, Dr. Eldredge presented a specimen of *hamamelis virginica*, gathered in the eastern part of the State during the month of October. He further spoke of its medical properties, and how largely it is used as a domestic remedy, under the name of Pond's exract. If the writer mistakes not, an officinal fluid extract is very generally kept in the drug-store, and as a vehicle in liniments, etc., cannot be surpassed.

B. J. Lillibridge, M. D.

Providence, R. I., January 26, 1885.

The Use of Aconite in the Treatment of Frost-bite.

Eds. Med. and Surg. Reporter:—

The treatment of frost-bite and its consequences, with the stimulating lotions recommended in the books, I relinquished as being unsatisfactory four or five years ago to cast about for something better. Believing the evil local effects of cold to be due to its action upon the nerve-ends in the integument, rather than to its direct action upon the living elements of the tissues, and that they are brought about through the reflex functions of the nervous system, it seemed that the best and quickest method of relief would be found in a remedy which would prevent the transmission of sensation to the nerve-centres, or prevent their reflexion. Of all the articles in the materia medica, aconite seemed to answer these requirements best; and the first trial fully confirmed the supposition.

For frost-bite, I have used it only in the second stage, the period at which the disease usually comes under the notice of the physician, after reaction has set in, when there is redness, swelling, and itching, burning, or tingling sensations, or all of them.

In this stage, the tincture of aconite root applied to the affected parts brings early relief to the disordered sensations; and with their disappearance, the swelling also abates quickly. The medicine should be applied freely with a camel's-hair brush, half a dozen or more times in succession, at such intervals as will permit it to penetrate the epidermis and dry on the surface between applications. After relief has been obtained, the remedy may be used three or four times daily until the parts have resumed a healthy feeling and appearance.

For the treatment of the annually recurring pernio, aconite is equally as valuable as in the initial frost-bite.

One of the latest cases in which I used it was in a young lady who had the outer side of one of the feet and the small toe frosted several years ago. She came to me last winter, saying that she had suffered several winters from the effects of frosted feet, and had tried everything that had been recommended without gaining any relief from the almost intolerable itching and tingling. She was requested to apply the tincture of aconite root to the diseased parts with a brush, half a dozen times daily, until her distress was ameliorated, and then only in the morning and evening. In the course of a month she reported that the medicine had acted like a charm, and she was completely rid of all suffering. With an occasional use of the remedy, she remained free from the effects of the disease until the approach of summer, when, as usual, they disappeared spontaneously, With the recurrence of cold weather this winter the disease reappeared, but its painful symptoms were again dispelled by aconite.

Another late case is that of a gentleman from the country, who had his feet so severely frost-bitten five years ago, that parts of the skin sloughed, leaving behind very irritable ulcers, which annoyed him a long time. Every winter since then there has recurred a most distressing pernio, for the relief of which he had tried turpentine and many other domestic remedies, as well as "medicine from the doctors," without deriving any benefit. After using aconite several weeks, he reported that it had given him more relief than anything he had previously used. Since then I have not heard from him.

As shown in the case of the young lady, aconite, like all the familiar articles mentioned in the books, nearly all of which I have tried, will not cure pernio permanently, but it will relieve better than any of them the distress attending it, from time to time, until the injury the nervous structures of the skin have sustained, will have been repaired by nature's process.

Of all the cases of frost-bite which I have treated with aconite in the last five years, some of which were of more than ordinary severity, none were followed by recurrent pernio. Whether this is due to the aconite, I am not prepared to say, because the number of cases is not large enough to determine such a question. Inasmuch as it can be decided satisfactorily only by comparing carefully a long series of cases treated with aconite with another series treated without it, I will rest contented with the simple statement that I have found this article to give better results, so far as my observation has extended, than anything else; and that, aside from its therapeutic effects, it deserves notice on account of the ease and cleanliness with which it can be used.

Reading, Pa. Daniel B. D. Deaver, M. D.

Mother's Marks.—To Disguise the Odor of Kerosene.

Eds. Med. and Surg. Reporter:—

For sake of record, this case is reported.

Mrs. M. A., primipara, aged 18, American, was delivered of a prematurely dead female infant on January 27, 1885. The child had been carried to full term, but the mother told me that its intra-uterine movements had been painful, even compelling her frequently to lie down in bed, until within two weeks before birth, when they suddenly ceased, with no cause apparent to herself.

This time agreed with the appearance of the child. The skin presented a macerated appearance, and its epithelium was removed in parts. The cranial bones rolled loosely under the scalp, while all the face was livid.

As to the cause of death, that was easily apparent, for the cord was tightly and triply wound about the abdomen at the level of the umbilicus.

There were what seemed to be bruises across the forehead and chin, which might possibly have been real "mother's marks." This Mrs. A. explained by her having been suddenly called to a hospital, some three months since, to identify her brother-in-law, he having fallen from a scaffolding and received frightful gashes across the face, just above the eyes and below the mouth.

Eds. Med. and Surg. Reporter:

In applying kerosene to the scalp for pediculosis capitis, Dr. William H. Bennett (of the medical staff at St. Christopher's Hospital for Children at Huntingdon and Fifth streets), usually adds a few drops of oil of bergamot to the ounce. This gives a pleasantly-smelling oily mixture, which the doctor also employs regularly in the cleansing of wounds.

News and Miscellany.

The Second Annual Meeting of the Ohio State Sanitary Association, Held at Columbus, Ohio, February 5 and 6, 1885.

The second annual session of the Ohio State Sanitary Association began at the Board of Trade Room, February 5, with the President, Dr. W. Morrow Beach, of London, in the chair.

After prayer by Rev. I. W. Metcalf, the welcome address was delivered by Dr. Gladden, in his usually happy manner. His witticisms provoked frequent outbursts of merriment. * * * * He said Columbus is probably no more guilty in violating sanitary laws than are other cities. Still, we have room to improve. The speaker said that until recently, after watching from his study the clouds of smoke arising from the Capitol, he had not realized how much smoke is generated in the manufacture of law. Gases more pestilent than smoke have been generated at the Capitol. A suitable topic for the future consideration of the Society would be, "The Influence of Bad and Poisonous Air on Legislators." You are engaged in the promotion of human welfare. Social science and sanitary laws are closely related. The interpretation of epidemics was formerly assigned to theologians. The sanitary laws are not explained by science. In admitting that there are laws, we surrender no part of our faith in the Power behind the laws. We have no less reverence for Him because He works by law, and not without plan. It is the business of this Association to make these laws better understood.

Dr. C. E. Beardsley, of Ottawa, responded to the address of welcome, thanking Dr. Gladden for his kind words, and speaking of the importance of the State having better statutes upon sanitary matters.

Dr. O. D. Childs, of Akron, read a paper on "Sewer vs. Surface Drainage, and Combustion." The doctor thought the surface drainage preferable to sewer drainage. But if we have sewers, the waste matter ought, by means of chemical science, to be reduced to harmless substances.

A very interesting paper on "The Tobacco Habit," was read by Dr. Lew Slusser, of Canton. He explained the action of nicotine, quoting from numerous able authorities, and referred to the action of the officials of the Annapolis Naval Academy and other public institutions in prohibiting the use of tobacco. A law has been passed in Switzerland, forbidding the sale of tobacco to minors, and a similar law is now being considered by the Legislature of Wisconsin. Such a law ought to be passed. It might be difficult to enforce the law, but it would in time have effect. The subject ought to be agitated by the people.

The Association passed a resolution urging upon city boards of health the importance of appointing men of thorough scientific acquirements to the positions of meat and milk inspectors.

Afternoon Session.

The Central Ohio Medical Association attended the afternoon session of the Association. Dr. Slusser's paper on "The Tobacco Habit" was discussed. Dr. von Klein, of Dayton, said he thought that tobacco, properly used, is harmless, and even beneficial. Dr. Slusser said the trouble was to fix the limit of use of tobacco. Prof. Nelson, of Ohio Wesleyan University, said that, from long and careful study of the effect of tobacco upon students, he could testify that its use by them is very injurious. Seldom, he said, had he found students using tobacco standing high in their classes, Dr. Reed, of Mansfield, earnestly condemned the use of tobacco, and said he thought it an outrage for any sanitarian to defend it. Dr. McIntyre, of Delaware, agreed with those condemning the use of tobacco. Dr. von Klein denied that tobacco causes any pathological effect upon the system.

Dr. G. S. Franklin, of Chillicothe, presented an able paper on "Sanitary Care of Privies." He proved to be an interesting speaker, and gave some very practical points and suggestions in his paper.

Dr. von Klein, of Dayton, followed with a paper on "The Disposal of Sewage and its Utilization." The doctor proposes to make fuel of all sewage. Samples of the fuel manufactured by Dr. von Klein's process from animal and human excrement were examined. They were square cakes of dark matter and light in weight. The doctor asserted that they were perfectly pure, and substantiated his statement by eating a portion of a cake. He positively refuses to patent his process, but wants to give it to the world free.

"The Relation of the Literary to Medical Col-

leges" was discussed by Professor Edward Nelson, of Delaware. He favored a co-operation between the literary and the medical colleges, with the hope of elevating the standard of education; of inducing college men to study medicine; of securing a study of physiology in the colleges and public schools, and of making public sanitary laws.

Dr. E. S. Ricketts, of Portsmouth, read a paper on the floods of 1883–4, and their sanitary results. He said the people feared lest a general illness would follow the rise of the waters, but there had been less illness in Portsmouth after the great flood than before, because the town had been thoroughly washed out. Dr. Owens, of Cincinnati, spoke of the flood in that city and the good health following, but attributed it to the cold spring, which held off the hot summer. Dr. Reed said that all towns which had been visited by the flood reported an improvement in health. Applause followed Dr. Reed's calling the flood a merciful dispensation. Dr. W. J. Scott, of Cleveland, thought the flood did good in washing out the soil, which had become saturated from the vaults. He called the cesspools the greatest abomination of the earth. He said filth would do less harm if thrown in the street than in the cesspool.

The evening session was opened by a paper on "The Hygiene of the Working Classes," by Prof. W. J. Scott, M. D., of Cleveland. The professor is an elderly gentleman, and has for many years studied the subject of which he spoke. He spoke of the many accidents and diseases that might be prevented. Machinery could be so guarded that accidents would be much less frequent. One of the most common sources of disease among working classes is the clothing saturated with sweat. Clothing, after becoming wet with sweat, is often thrown into closets, and becomes very offensive. Shop-girls are extremely careless about these matters. We of modern times are much behind the people in ancient times. The baths of Rome and Pompeii have never been surpassed. It would be a good plan to have public baths, at which all might become clean.

Dr. Slusser commended the ideas expressed by Dr. Scott. He thought that medical men do not pay enough attention to these important subjects. The attention of the people ought to be called to them. Farmers, as well as those in cities, need to study the laws of hygiene.

Dr. von Klein thought a law ought to be passed, requiring manufacturers to protect their machinery.

Dr. R. H. Reed said the troublesome question is, How will you compel people to keep clean? He referred to the many difficulties in the way, and to the objections to public baths.

Dr. Franklin described the bath houses for public use that have been established in New York city, which have been very successful.

Dr. Beach, President of the Association, referred to the use of emery-wheels in Springfield, where, he said, the operators of the wheels sometimes die after a few weeks' work, and rarely live more than two or three years.

Mr. J. J. Janney said the emery dust could be prevented from scattering in the air, by an apparatus invented for the purpose.

Prof. Nelson, of Ohio Wesleyan University, said the people would not keep themselves clean unless compelled to do so. At Delaware an attempt had been made to interest the workingmen in popular lectures. The professor asked Dr. Scott whether, in the popular lectures given in Cleveland, any sanitary measures had been treated. The doctor replied that sanitary subjects had not been considered, but scientific subjects had been treated, and the lectures had been very successful.

Dr. Hill, of Neville, spoke of the poor ventilation in school rooms, and inquired how, in small towns and in the country, where lectures could not be given, the people could be interested in sanitary subjects.

Dr. Silver, of Sidney, replied that the country press could be used as an educator.

Dr. C. R. Reed spoke of the importance of providing better homes for the people.

Dr. Ricketts thought education the only means by which the people could be taught the importance of cleanliness.

Dr. Bumdage described the bathing system in use at the Ohio Soldiers' and Sailors' Orphans' Home at Xenia.

Dr. von Klein described the public baths that he said are found everywhere in Russia. He said that if such a people as the Russians had learned to bathe, he could see no reason why the Americans can not be taught to do so.

The following resolution, offered by Dr. Franklin, of Chillicothe, was adopted:

Resolved, That it would be a great benefit to the progress of sanitary knowledge, and is recommended by this society, to establish local sanitary societies in each city, town, and village of this State, for the purpose of the diffusion of such knowledge and its realization in practice; and

Resolved, That transparent slides, illustrating sanitary subjects, to be exhibited by the magic lantern, are greatly be desired in the diffusion of this knowledge.

The association, feeling that it would not have enough time at its disposal, was compelled to decline an invitation from Prof. Orton to visit the State University to-day.

FRIDAY MORNING, FEBRUARY 6.

The morning session was opened by prayer by the Rev. G. W. Lincoln, after which the following officers were elected for the ensuing year:

President—Prof. Ed. Orton, LL. D., Columbus.

First Vice President—Prof. W. J. Scott, M. D., Cleveland.

Second Vice President—Dr. D. R. Silver, Sidney.

Third Vice President—James Allison, esq., Cincinnati.

Treasurer—Prof. John Simpson, Ph. D., Mansfield.

The secretary being elected for two years, was not elected this year.

After the election of the standing committees, the association, upon motion of Professor Nelson, appointed a committee to correspond with prominent physicians of the State, urging the organization of local sanitary societies, in accordance with the resolution of Dr. Franklin, adopted last evening. Dr. J. E. Reeves, of Wheeling, W. Va.; Dr. John B. Hamilton, Surgeon-in-Chief of

the United States Marine Hospital Service; and Dr. A. N. Bell, editor of the *Sanitarian*, were elected honorary members.

The first paper to-day was read by Dr. D. R. Silver, of Sidney, on "Heating and Ventilation." The speaker treated chiefly of the exhaustive method of ventilation, by which the lower cold stratum of air is withdrawn from the room. Dr. Silver is a warm advocate of this system of ventilation. The paper elicited discussion from Mr. Janney; Dr. Reed, of Mansfield; Professor Search; Dr. Reed, of Middleport; Dr. Hyatt; Dr. Beardsley; and Dr. Hamill, of Columbus.

Dr. C. B. Reed, of Middleport, read a paper on "Compulsory Vaccination," arguing that the State, for the benefit of its citizens, ought to require by law the veccination of everybody. Remarks upon the subject were made by Drs. Beach, C. R. Reed, Landon, Hyatt, Baldwin, and McIntyre. Dr. Baldwin said that a compulsory vaccination law in England had proven unwise, and had aroused opposition to the principle of vaccination. Mr. Janney was opposed to the passage of such a law.

AFTERNOON SESSION.

At the opening of the afternoon session, thefirst paper was read by Dr. R. Harvey Reed, of Mansfield, on "Climatic Changes in Ohio from the Destruction of the Forests and the Drainage of the Land, and its Effects on the Health of the People."

Professor Orton read the second paper, on "What Shall be Done with the Sewage?" The professor said the question is the riddle of the modern Sphinx. It enters into and complicates every sanitary problem. To answer it so as to satisfy the demands of the public health on one side, and the various economic interests that are involved on the other, is the main end and object of what we call sanitary science. The answers that civilization has so far furnished are all fractional and crude. The term sewage may be considered co-extensive with the products of human waste, which are hateful to every sense. They cannot be retained about our premises without offense and danger. The growing urgency of the question arises from the fact that never before in the history of the world has the increase of cities and towns been so rapid as in the nineteenth century. In our best practice, we are pouring these human products into the nearest drainage channels, without the slightest attempt at precipitation, purification, or utilization. By far the larger portions of our population do nothing with it systematically, but allow it to accumulate around and beneath them.

What ought not to be done with the sewage? In the first place, it ought not to be emptied, in its crude and gross form, into our rivers. Even if sewage could be conveyed by the rivers without ruining them as sources of water-supply, the excrement portion of the soil ought not to be emptied into the water. The poison of the rivers is the life of the soil. The waste products that are a source of danger and death elsewhere are shorn of their powers of evil when they touch the soil. If our best practice falls under sanitary and economic censure, much more must the rude ways of our smaller cities and villages be condemned. The theoretical answer to the question, what ought to be done with the sewage, is easy and obvious. It ought to be returned to the soil from which it was originally derived. It is idle to say that this cannot be done. It is done to-day, and has been done for ages, in the great hives of mankind—China and Japan—and the results are assuring to a high degree. Our ideas of propriety and decency are such that it would be impossible for us to adopt the methods of China. The complete, systematical, self-consistent answer belongs to the future—a future removed from us by decades, if not centuries; but we must do the best we can.

There is no answer that will suffice. There seems to be a great deal to be said in favor of dry removal, by which the excreta are systematically removed at public expense. Sewage irrigation farms have proved very successful in various parts of the Old World, and on a smaller scale in America. The separate system of sewers seems to offer great possibilities of public service. The simplest thing that we can insist upon, and one which may be the beginning of an extended reformation, is the exclusion of human waste from the soil. We ought to be able to require the cementing of cess-pools and vaults.

The paper, which was a very lengthy one, covering thirty-one pages, closely written, was written in Dr. Orton's very interesting style, and was listened to very attentively.

Dr. Reed crystallized his paper into the following conclusions:

"1. From the destruction of the forests, we have more wind (as shown by the Signal Service records), more dust; more sudden dashes of rain, resulting in more sudden changes from one extreme to the other, both as relates to temperature and moisture.

"2. From the immense amount of artificial drainage, and the improvement of natural watercourses, there is a much more rapid transmission of water from the peripheras to the great trunks and basins.

"3. These two causes combined act: 1, in removing the surplus surface water supply more rapidly; 2, by the decidedly increased evaporation; which together rob the natural regulators, and lessen the common supply of springs and wells, which in the latter require deeper average penetration (as is shown in the records of well-driving firms), and in the former of partial or total failure of springs which once were strong.

"4. These changes have been followed with a decrease of all forms of malarial diseases, and an increase of typhoid fever, together with a very decided increase of all forms of catarrhal troubles and their acknowledged common sequelæ—deafness and chronic pulmonary troubles.

"Finally, the author is of the opinion that in addition to all these, the increase of wind and dust is a decided factor in the propagation and spread of all forms of contagious and zymotic diseases, and furnishes a rational explanation for the frequent occurrence of the so-called sporadic cases of contagious diseases."

After the reading of Prof. Orton's paper, the President, Dr. Beach, of London, delivered his retiring address on "Contagions and Epidemics in America," which was a scholarly, interesting,

and historic paper, characteristic of the great man that he is.

Mr. James Allison, of Cincinnati, Vice-President of the American Master Plumbers' Association, sent a very interesting and practical paper on "The Tenement Houses of Cincinnati." "An extremely important element in the sanitary future of Cincinnati is a judicious and sufficient building law. For so long as buildings *may* be erected according to the mercenary caprice of ignorant owners, unscrupulous architects, and shoddy builders, all efforts, however well devised, towards sanitary improvement, will prove inefficient."

Owing to the lateness of the hour, Professor E. H. Hyatt's volunteer paper on "The Cholera Epidemic in Europe in 1884, and its probable entry into our country the coming season," was read by title, as the Doctor had to take the train home.

The following resolutions were adopted:

Resolved, That this Association endorse the bill presented by Senator Palmer in the United States Senate for the prevention of the introduction and diffusion of contagious and infectious diseases in the United States, and to promote the general sanitary welfare of the people, and desire that our Representatives in Congress give it their kind consideration and support.

The foregoing resolution was presented by Mr. James Allison, and the Secretary instructed to inform the Senate and House of Representatives of the United States of America of the action of this Association.

The following preamble and resolution was presented by Prof. W. J. Scott, of Cleveland:

WHEREAS, We may expect, from past experience, the occurrence of an epidemic of malignant cholera in this country the coming summer; and as our position in relation with Eastern cities, in consequence of most of the ways of travel from east to west passing through two States and waterways, by which our State is half surrounded, and in which our dangers are greatly enhanced; therefore,

Resolved, That it is the sense of the Ohio State Sanitary Association that in view of the threatened epidemic of cholera in our country and in our State, the Legislature be urged to provide by law against the invasion of the State by this pestilence, so far as it can be done, by the application of sanitary measures, wisely adopted and vigorously executed. To do less than this, being thus forewarned of danger, is simply criminal neglect of the health and lives of our citizens, to say nothing of loss to the business interests of the State.

Dr. von Klein, of Dayton, presented the following resolution:

Resolved, That this Association declares that cremation or incineration of the human dead is a sanitary measure.

After the adoption of the above resolutions, the Association adjourned to meet in Columbus next February, 1886.

The meetings of the Association throughout were interesting and instructive, and resulted in the addition of twenty-six new members from different parts of the State.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, January 1 to 31, 1885.

Stoner, G. W., surgeon. When relieved to proceed to Washington, D. C., for duty as chief of Purveying Division, January 16, 1885.

Benson, J. A., passed assistant surgeon. When relieved to proceed to Chicago, Ill., for duty, January 12, 1885.

Carmichæl, D. A., passed assistant surgeon. When relieved to proceed to Cairo, Ill., for duty, January 3, 1885.

Ames, R. P. M., passed assistant surgeon. When relieved to proceed to New York, N. Y., for duty, January 14, 1885.

Urquhart, F. M., passed assistant surgeon. To proceed to Norfolk, Va., and assume charge, January 12, 1885.

Brooks, S. D., assistant surgeon. To proceed to Evansville, Ind., and assume charge, January 14, 1885.

Carrington, P. M., assistant surgeon. To report to surgeon-in-charge, St. Louis, Mo., for temporary duty, January 17, 1885.

PROMOTION.

Stoner, G. W., surgeon. Promoted and appointed surgeon by the Secretary of the Treasury, from January 16, 1885, January 14, 1885.

APPOINTMENT.

Carrington, Paul M., M. D., of Georgia, having passed the examination required by the regulations, was appointed an assistant surgeon by the Secretary of the Treasury, January 16, 1885.

Undertakers' Law.

There is occasionally an undertaker who refuses to complete arrangements for burial until his bill for services is paid, and in New York there was a few days since an instance of the kind. The undertaker in this case was engaged to bury a child and agreed to, securing the burial permit necessary. He had, however, an unpaid bill of $16 for previous services, and he refused to allow the funeral to proceed until he had been paid this amount. Complaint was then made by the family to the officers of the Bureau of Vital Statistics, and the Registrar sent word to the undertaker that he must either proceed with the funeral or surrender the burial permit. Upon receipt of this message, the matter was arranged, and the funeral proceeded.

The Hydrangea Arborescens.

The value of this native plant in renal affections was first made known to the medical public by the former editor of this journal, Dr. S. W. Butler. Recently Lambert & Co., of St. Louis, have combined the active elements of the plant with lithia in a preparation called "Lithiated Hydrangea," which unites the virtues of both these remedies. In the *Chicago Weekly Review* two cases of rheumatic gout with renal complications are reported by Dr. F. S. Senier, of Waukesha, Wis., where this preparation in doses of a drachm, thrice daily, largely diluted, acted with prompt and satisfactory effect. The combination seems to us a happy one.

A Jefferson College Professorship.

The resignation of Professor Mallett, who occupies the chair of chemistry in the Jefferson Medical College, which takes effect in April, will cause a lively contest for the position, which is worth about $7,000 a year. Among the best-known applicants are Professor Henry Leffmann, who is now demonstrator of chemistry in the college; Professor John J. Reese, and Professor Geo. F. Barker, of the University of Pennsylvania.

Medical Electric Machines.

The general advance in electrical science of recent years has made itself felt in medical as well as other electrical apparatus. Some of the most satisfactory instruments are those manufactured by the Jerome Kidder Co., of New York. They have received a number of awards for superiority, and well deserve it for their fine finish and durable powers.

Fire at Blockley Insane Asylum.

On the evening of Thursday, February 12, a most disastrous conflagration occurred in the insane department of Blockley Almshouse, in this city. It will be officially determined where the responsibility for the fire belongs. Some twenty of the insane patients lost their lives, some being burned to death, and others so severely injured as to cause death.

Items.

—Dr. George Taylor Robinson, of Camden, has received his commission as assistant surgeon of the Sixth Regiment, National Guard of New Jersey.

—In the *Annals of Surgery*, January, 1885, Dr. Charles B. Keetly, of London, publishes a paper on removal (by scraping out) of the marrow of long bones, and especially on this proceeding as a treatment of osteo-myelitis; also on the same followed by the local application of corrosive sublimate solution and iodoform.

—Before the New York Pathological Society (December 10, 1884), Dr. John A. Wyeth presented a portion of the acromion process and spine of the scapula which he had removed for osteitis the result of traumatism. The point of interest in the case was the fact that complete healing of the wound and recovery took place under one dressing. Antisepsis was observed.

—Before the Liverpool Medical Institution (Dec. 4, 1884,) Dr. Rich showed the heart of a man who had died of pneumonia shortly after admission into the Royal Infirmary. It was not known until the necropsy that he had suffered from heart disease. There was a small aneurism of one of the cusps of the aortic valve, which had produced, by contact with the mitral valve, a patch of atheroma, now dilated into a considerable aneurism of the mitral valve, bulging into the auricle.

—Mr. Payn, in his literary reminiscences, tells the following story: During his Cambridge career, he made the acquaintance of De Quincey, and in his account of this extraordinary man, tells how, lunching with the De Quinceys, "I was asked what wine I would take, and not caring which it was, I was about to pour myself out a glass from the decanter that stood next to me. 'You must not take that,' whispered my hostess, 'it is not port wine, as you think.' It was, in fact, laudanum, to which De Quincey presently helped himself."

—J. Forster (*Dingl. Polyt. Jour.*, No. ccli., p. 170,) has experimented with the view of determining the action of boracic acid upon the animal system, and concludes that the use of boracic acid as a preservative for articles of food is a practice prejudicial to the digestive organs of those using such food. The boracic acid increases the excretion of nitrogen and solid matter in the fæces; and this is experienced when so small a quantity as seven or eight grains a day is ingested. This action is, moreover, in direct proportion to the quantity of the acid taken.

—Professor Da Costa recently exhibited a case at his clinic, in which an attack of facial erysipelas was cut short in a remarkable manner by a hypodermic injection of a third of a grain of hydrochlorate of pilocarpine. The patient received a blow in the face one Wednesday night, and the next morning the upper part of his face was erysipelatous, the inflammation extending rapidly up on the brow, and over to the other eye. On the Thursday afternoon, he received the injection; and, after profuse sweating, the tumidity of the eyelids subsided, and, by the next morning, he could open both his eyes. The disease did not return, and he became at once convalescent, but took iron for a few days before going home again.

—A lay contemporary states that a man in Minneapolis escaped death in a singular manner. A druggist there put up by mistake an ounce of tincture of aconite in a prescription brought to his store by a young man whose residence was unknown. Discovering his error soon afterwards, he endeavored to find the man to avert the mischief. The police were notified, and the officers of the District Telegraph Company sent in search of the party. In addition posters were stuck throughout the city notifying "Charlie Johnson" to call at the drug store at once. On the following day Johnson walked into the drug store and inquired what he was wanted for. He had taken the entire contents of the bottle, but fortunately the tincture was very weak and he was not injured.

—A short time ago, in Paris, a female jeweller was brought up for manslaughter under the following circumstances: A mother, with a little girl, asked her to pierce the child's ears. Madame Massard had frequently seen her husband perform this operation, and complied with the request. The child left the shop, wearing a pair of gold ear-rings. One hour later on, her ears, then her neck, became swollen; she was taken to one of the Paris hospitals, where she died the same night. Madame Massard had pierced the cartilage instead of the lobe of the ear, and the wound became gangrenous. A charge of illegally practicing surgery was added to that of manslaughter, but was withdrawn; and the prisoner was fined $10.00, and condemned to pay $3.00 damages.

ORIGINAL DEPARTMENT.

LECTURE.

THE ASIATIC CHOLERA.*

BY HUGO ENGEL, A. M., M. D.,

Professor of Nervous Diseases and Clinical Medicine at the Medico-Chirurgical College of Philadelphia.

LADIES AND GENTLEMEN: About a month ago the Ph ladelphia Society for Organizing Charity, in whose hall we are now assembled, invited me to deliver an address to-night on cholera. This dangerous epidemic disease, whose cradle stands in the marshy regions of the delta of the sacred Ganges river, several years since made its appearance in the neighborhood of Calcutta, and in Egypt. Last year it began its ravages in Toulon and Marseilles, thence spread south, and thousands of human beings fell victims to the fell destroyer in sunny Italy and rich Spain. But it was not until, a few months since, the gay capital of the French Republic, Paris, was invaded by the dreaded malady, that civilized humanity really awoke to the threatened danger. For if such a center of human industry as Paris is once infected, if the Asiatic disease once takes hold of a city, to which in the interest of modern civilization thousands yearly flock from every part of the known world, and whence thousands return to their native lands, the further spread of the disease-bearing contagion to every country of the globe where human energy has established intimate commercial relations, simply becomes a question of time. For like Ahasverus, whom the curse of Christ sent wandering for thousands and thousands of years from one end of the earth to the other, from the South pole to the North pole, from the eastern coast of the Pacific across Asia, Australia, Europe, and Africa, over the mighty Atlantic, to the western coast of America and back to Asia, until the day when all mankind will have to appear before His throne and bow to the final judgment—like this ever-wandering Jew, the epidemic Asiatic cholera travels along the paths of commerce, follows the highways of nations, and thus step by step invades every place where the industry of men seeks to form a connecting link in the great chain of international intercourse.

Formerly, ere steam whirled us rapidly across a continent, when the slow-sailing ships and the camels of the eastern caravans were the only means of human intercourse between the East and West, the South and North, the dreaded malady marched from country to country with the same slowness that characterized the commercial relations of nations. But in modern times the death-dealing disease follows the roads of commerce with the rapidity with which in the present era one land maintains its relations with another.

One significant fact was early learned from the observation that the cholera always progressed from one locality to another in the manner of human intercourse. The poison causing the disease could not be in the atmosphere, otherwise its spread would have taken place in the direction of prevailing winds, and the infection of localities would have happened sooner than by human means an article may be transferred from district to district. There is no case on record where the malady had developed itself *eo ipso*, and those in-

*A lecture delivered January 5, before the Philadelphia Society for Organizing Charity.

stances which used to be cited as examples proving the possibility of the outbreak of cholera without its pathogenic contagion having been imported, have since been demonstrated as fallacious. If science has established one indisputable fact, it is that the source of the disease comes from the Ganges, and the importation of the infectious material is the first and most essential condition for the appearance of cholera in any locality. But that the air did not contain and spread the contagion. and that this had to be carried to a district ere the latter could be infected, were two truths which proved to the scientific world that were the agent causing the disease but known and tangibly demonstrated, the prevention of its introduction would become a probability. The main point was, therefore, the discovery of the pathogenic element of the infectious material which produced the cholera.

It is my intention to-night to give you a full resumé of all that to-day is known concerning this disease. Should I, therefore, occupy a little more time than that usually allotted to a lecturer, I hope you will pardon me if I assure you that you will leave this room to-night in the possession of all the knowledge that the most accomplished physician may have to-day of this disease.

For a better understanding, as not all my hearers are physicians, I may be permitted first to give you the history and a description of the disease before I consider the most vital point—its cause.

The name cholera is derived from the Greek $\chi o\lambda\acute{\eta}$, bile, and $\rho\acute{\epsilon}\omega$, to flow. Epidemics of the disease are known to have occurred at various times for several centuries in the Indian Archipelago. But it was not until 1817 that the outbreak of a violent epidemic in Jessore, in Bengal, specially drew the attention of the medical world to the disease, which at that time caused the deaths of thousands of Europeans and native-born, by spreading nearly over the whole of British India. For three years the malady continued its ravages, invading Ceylon and the neighboring islands, and then it suddenly assumed still greater proportions by infecting China and Persia. 1823 it reached Russia, and from that time on it continued steadily its march west, fresh epidemics appearing at intervals in India, and giving new food to the disease. 1830, a new outbreak in Persia and along the shores of the Caspian Sea finally extended into Europe, and caused in the whole Russian empire immense ravages, the mortality being so great as to produce the utmost consternation all over Europe. Soon the rest of Europe became invaded, and during the year 1832 its disastrous effects were felt in Great Britain. Then the contagion crossed the Atlantic and the continent of North America was also infected, while in 1835, Arabia, Turkey, Egypt, and the whole of North Africa, gave the proof that the epidemic, starting in 1817 in Asia and continuing up to 1837, whithin these twenty years had visited a large portion of the world.

In the year 1841, another great epidemic broke out in India, and soon extended over a still wider area than the former. Entering Europe in 1847, it passed through Russia and Germany, over to England, and thence to France, whence it was carried to our country, and subsequently to the West Indies. This epidemic seems to have been yet more deadly than the first, especially in Great Britain and France. A third great outbreak took place in 1850, and made its appearance three years later in Europe, where it was specially destructive amongst the Crimean armies, but less violent in England. This epidemic was, however, specially severe in North and South America. Since then, minor and more local epidemics have at times been observed in Russia, Turkey, and Western Asia; but the disease never again obtained a foothold in Europe, until the outbreak about two years ago in Egypt and Calcutta caused its transportation to Toulon, whence it spread to Italy and Spain, and ultimately reached Paris, where it still rages, though, on account of the cold weather, at present not with great vehemency.

This malady, since the disappearance of the Plague or the Pest, and since the cessation of the grave epidemics of small-pox, probably more dreaded by the people in general than any other infectious disease, is usually characterized in what seems to be its normal type by three stages.

The first stage, or that of cholera-diarrhœa, shows itself simply by the symptoms of a common, mostly painless, diarrhœa, which, generally making its appearance after an error in diet at a time when the cholera is epidemic in a locality, is but too often neglected. It is exactly like a common summer-diarrhœa, and in its beginning rarely associated with vomiting. If early attended to, the patient generally completely recovers within one or two days, and is exempt from the graver disease during the whole epidemic. But if interfered with too late, or left to itself, one of two things will happen: either death sets in rapidly by the diarrhœa suddenly assuming all the characteristic signs of genuine cholera discharges, accompanied by vomiting, or gradually the other stages of the disease develop themselves.

In the second stage the diarrhœa continues, but

increases a great deal in frequency, and the discharges, greatly augmented in quantity, take on the appearance of rice-water. Still more frequently there is no prodromic stage of common diarrhœa, but suddenly, often during the night, the most violent diarrhœa sets in, the evacuations having from the very beginning the character of rice-water, consisting of large quantities of disintegrated epithelium and specially peculiar by the total absence of all the constituents of bile. The rice-water-diarrhœa has scarcely lasted one or more hours, when copious vomiting of the same rice-water-like masses, and accompanied by intense pain in the region of the stomach, and great thirst, set in.

With the appearance of this vomiting, the graver symptoms follow each other in rapid succession, and what might have first seemed to the uninitiated an attack of cholera morbus soon presents to the trained eye the picture of the justly dreaded Asiatic disease. Cramps of the legs, feet, and of the abdominal muscles, cause the unhappy sufferer the greatest agony; and while the mind continues clear and the more feels the torturing pains, the fatal stage of collapse is ushered in.

The face assumes a cadaverous hue, the nose becomes pointed, the eyes sink back into their orbits, deep dark rings surrounding them, and the blue lips, blue finger-nails, and ice-cold, dry, and wrinkled skin all denote that the excessive drain has emptied all the vital channels of their fluids, and that life must be despaired of, if the symptoms do not soon ameliorate. More and more pinched appear the features, the external integument assumes a bluish or purplish tint, colder and colder becomes the body; the pulse at the wrist is imperceptible, and the vox cholerica, that peculiar hoarse whisper which generally foretells the fatal issue, already seems to come to us from beyond the grave. Often death sets in in less than one day, and at the beginning of an epidemic cases are not rare, where the collapse is so sudden and so complete, that life departs in less than one hour.

It still happens at times that recovery takes place even from the stage of collapse. Then reaction sets in. The dangerous symptoms cease; the heart regains its power; in some unaccountable way the vessels once more become filled with fluids, the reëstablished circulation causes the reappearance of the pulse, and the disappearance of the varied hues of the skin; the bodily heat is restored, and vomiting no longer harasses the sufferer. The diarrhœa sometimes still continues for a while, or the patient falls into a typhoid condition, in which he may be again brought near to the grave. As a general rule, convalescence is the slower and relapses occur the easier, the further the patient had progressed in the stage of collapse. Occasionally, also, various complications arise, which still more increase the danger to the victim; but with rare exceptions the disease presents the picture as described, only the duration of each stage varying in the different individuals attacked.

That so grave a malady, causing such enormous ravages, should have attracted the attention of medical minds from its first appearance, may be presumed. The most careful researches were made with the intention of discovering the morbid agent which caused this dangerous epidemic disease, but for a long time in vain. Then, about fifteen years ago, an observation was made which promised a great advancement in our knowledge of infectious diseases.

At the boundary between the animal and vegetable kingdom there is an immense empire of minute beings, too small to be visible to the naked eye. So difficult becomes here the distinction between the animal and the plant, that even experts for a long time were in doubt to which of the two kingdoms these micro-organisms belonged. To-day the majority of observers incline to the belief that they pertain to the vegetable kingdom. There are two great subdivisions of these microbes, hyphomyceti and schizomyceti. The first so-called moulds or fungi, multiply mainly by the aid of spores. They are parasites, many of which give rise in the human being to diseases of the skin and of the mucous membrane, as favus, thrush, etc. That they do so, is to-day denied by no scientific authority; their destruction by appropriate remedies is at once followed by a disappearance of the disease. The propagation, on the the other hand, of the schizomyceti takes place mainly by division. It is with the last, that we have to do in cholera.

Most of the schizomyceti have a rod-like form, and as a rod, in Greek is called *Βακτήριον*, they have received from science the name of bacteria. But not all bacteria have exactly that shape, and according to their form, they have been arranged in six classes, called—

1. Micrococci or cocci, characterized by their circular shape.

2. Bacilli, by which term are understood all rod-shaped bacteria, whether short or long.

3. Bacteria proper, as which science recognizes only the very shortest bacilli.

4. Vibriones, also rods, but of wavy shape.

5. Spirilli forming short, stiff screws; and

6. Spirochaeti, which appear as long flexible screws.

As many of my kind hearers may not be thoroughly informed concerning these minute beings, a special kind of which forms the pathogenic element, the real cause of Asiatic cholera, permit me to mention a few data regarding them:

Of one single bacterium, which during the first hour has divided into two, these within another hour into four, and within three hours into eight, after twenty-four hours have already become sixteen and one-half millions, after two days two hundred and eighty-one and one-half billions, and after three days forty-seven trillions. If in this manner the development and multiplication could progress unimpeded, the breed of bacteria, springing from one germ of about $\frac{1}{500}$ mm. in length, and $\frac{1}{1000}$ mm. in thickness, within less than five days would completely fill all the oceans of the earth; and the descendants of one single micrococcus, whose weight is so little that sixteen hundred millions of them weigh but one grain, would within three days reach the enormous weight of fifteen million pounds.

If nature had placed no impediments in their way, how soon would these diminutive little beings overpower every living organism! But they can propagate only under certain conditions. For instance, their most common kind, the septic bacteria, cannot obtain sustenance from the healthy living organism. For most others the first condition necessary for their development is their entrance into the living human or animal body; and what difficulties they have here to overcome, may be judged from the fact that in the blood and tissues of *healthy* beings not a single bacterium has ever been found.

But the enormous propagation of septic bacteria at once begins when death has interrupted the mechanism of life, and the organized tissue having ceased its motion, is decomposed, decays, ferments and putrefies. And it is to-day a recognized fact, undisputed by any authority, that the process of putrefaction, by which the dead organized substance loses the form and the composition of its constituent parts, is not only accompanied by the development of bacteria, but, in fact, caused by it and kept up by it alone.

And not only decay and putrefaction are caused by these microbes; there are many chemical processes, known by the name of fermentations, which the celebrated researches of Schwann, Pasteur, Ferd. Cohn, and others, have proven to depend upon the vital process of bacteria, or other micro-organisms related to them. For instance, alcohol fermentation, the process by which sugar is changed into alcohol and carbonic acid, is caused by the activity of the yeast-plant. When fermented fluids become acid, the fact depends upon the change of the alcohol they contain into vinegar; and as Pasteur has demonstrated, the excitor of the vinegar fermentation is another bacterium. If milk becomes sour, a rod-shaped schizomycete is responsible for it; and the peculiar phenomena known as pigment-fermentations, owe their origin to a micrococcus. The remarkable incident, which in times passed by caused so much religious superstition, viz., that on food, and especially on the holy wafer used in communion, suddenly appeared a drop of blood, or rather of red coloring matter, simply depends upon the decomposition of animal and vegetable substances produced by the same micrococci (Monades prodigiosæ, Ehrenberg). Many other discolorations brought about in moist air on potatoes, cheese, boiled eggs; etc., all originate in the action of micrococci; while the bluish and yellowish tint sometimes assumed by milk, and the green and blue color of pus, are produced by rod-bacteria.

But the researches of modern times have demonstrated the fact with positive, undoubted certainty, that the activity of bacteria is not limited to the decomposition of *dead* organic substances, but that it also extends its fiendish power to the destruction of the processes of life of the highest organized beings—the human race and the animals nearest to it. Amongst many innocuous schizomyceti, there are some pathogenic kinds, which not only live and easily propagate in the interior of the living organism of warm-blooded animals, but which even seem to find there their only conditions of existence.

Many years ago the suspicion was awakened that some of the infectious diseases are caused by living organized poisons. It is remarkable that in 1840 Henle published in his work a series of logical deductions, based upon scientific facts, by which he proved the necessity of a *contagium vivum* being the pathogenic cause of infectious diseases. What he then supposed, to-day is proven.

But a new impetus was given to these researches, when facts became known which showed that parasites were far oftener responsible for morbid conditions than had ever been dreamed. Certain diseases of the skin and of the mucous membranes (as favus, herpes tonsurans,

aphthæ, etc.), were proven to be caused by parasites ; and Virchow finally demonstrated that a very dangerous internal disease, trichinosis, hitherto supposed to be due to a miasm, was produced by the immigration of a highly organized animal organism, the trichina spiralis.

As logical conclusions, based upon scientific data, pointed to a contagium vivum, and as the deffnite proof had been adduced of parasites acting as morbid agents in and upon the human body, the idea more and more took hold of the medical profession, that in every infectious disease a living contagium was the pathogenic element. And during the last decade—especially, however, during the last two or three years—discoveries have been made, establishing the correctness of this view.

The first discovery of this kind Pollender and Brauell made, independently of each other, by detecting peculiar small rods in the blood of animals and human beings suffering from anthrax. Thanks to the labors of Davaine, Bollinger, Klebs, Pasteur, and especially Koch, it is now generally recognized that these small rods are genuine bacteria, species bacilli, and that they are really the pathogenic cause of anthrax.

Investigators next succeeded in demonstrating the constant presence of certain bacteria in all morbid processes belonging to the great group of septico-pyæmic diseases.*

Obermeyer then showed the presence of innumerable screw-bacteria in the blood of persons suffering from relapsing fever. This fact made a profound impression upon investigators, and from all sides proofs were soon adduced. As further acquisitions, definitely proven, may be considered the discovery of lepra-bacilli by Hausen and Weisser, of the typhoid-bacilli by Klebs, Eberth, Koch, of the tubercle-bacilli by Koch and Baumgarten, and of the bacilli of glanders by Schütz and Israel. These micro-organisms can be easily demonstrated in recent cases, if the methods of research described by their authors be employed ; and their constant occurrence in the diseases mentioned is generally acknowledged.

All these discoveries had been made, when the outbreak of cholera in Egpyt and Calcutta gave scientists an opportunity carefully to investigate this disease. The German government sent a commission to the infected regions. At the head of it was a man already well-known in science as the most eminent authority on bacteriology, Koch, and he at once employed all his energy for that one purpose. It will here be necessary for me to explain to you some of the difficulties which have to be overcome in these investigations.

Most bacteria so greatly resemble each other in their shape, that only the most expert, and he not always, can recognize the species. For instance, those causing glanders, the fatal disease of horses, those of tubercle, of anthrax, and of cholera, at some time or other have nearly the same shape. One appears a little thicker, another more rounded at one point, a third slightly longer ; but if we remember that they are about the $\frac{1}{1000}$ of an inch in thickness, and the $\frac{1}{500}$ of an inch in length, we may imagine how slight the difference must be, when one is an immeasurable bit smaller or thicker. Whoever, therefore, thinks that all that is necessary to discover a specific bacterium in any disease is the microscopical examination of the diseased tissue, will make a great mistake. For in most cases not only one but several species of these microbes are met with. Whenever a specific bacterium has invaded the tissues and caused inflammation, and when later decay and mortification set in, the processes last mentioned are caused by other micro-organisms, which soon deprive the specific microbe of its vitality. It is thus that nature sets a limit to their ravages. We usually find, therefore, the specific microorganism pure only in very recent cases of infectious diseases. Then, if the bacterium has selected as its favorite seat the intestines, we have another difficulty to overcome ; for in the bowels are normally met with different species of animalculæ, which are, however, innocuous.

The first difficulty, therefore, is to determine which of the bacteria observed is the specific one. When we have succeeded in this, the important question arises, is it really a new and specific bacterium, or some variety already known ? It would have been impossible even to arrive at a decided result in this respect, and the science of bacteriology would still be where it was ten years ago, had it not been for Koch's discovery of pure culture. This process is as follows:

A soil composed of gelatine, of which it is kuown that it is perfectly aseptic, *i. e.*, completely free from any micro-organisms, is placed on a convenient glass plate, or in a reaction-glass, such as are used for chemical analyses. Upon the surface of this fertile soil the suspected bacteria are spread, and their development is then watched. It has been discovered that every species grows under different conditions and in a different man-

*Introductory of Prof. H. Engel, delivered in the aula of the Medico-Chirurgical College, at the opening of the Winter Course, October 6, 1884. Reprint MED. ARD SURG. REPORTER, October 12, 1884.

ner. For instance, one kind will develop only under a temperature of 101° to 104°; another one will lose its vitality if exposed to a greater warmth than 99° Fahrenheit; again, another will not at all multiply except on a certain albuminous soil, consisting of the serum of the blood; another must have the white of an egg; another, beef-tea; another the starchy base of a potato, etc., etc., before it can ripen. Then the various methods of coloring employed by microscopists to show plainer certain micro-organisms, so that they may be distinguished better from cells and other parts of the tissues in which they reside, act in a very different manner upon the various species. Thus, for instance, the bacilli of glanders, tubercle, and anthrax look alike, and they are stained by the same coloring material; but while those of anthrax take on the coloring without difficulty, those of tubercle and of anthrax have to be exposed to its influence for a considerable length of time. Then the bacilli of anthrax after having been thus stained, easily again yield their color under the influence of acids, but those of tubercle resist even the action of sulphuric acid. I mention these instances to show how, in the case of the micro-organisms causing tubercle, of those producing anthrax and of those giving rise to glanders, a distinction between them can be made only after their behavior under the influence of coloring material has been determined.

But neither the knowledge of the soil in which they grow, nor that of the conditions most favorable to their development, nor that of their response to the action of dye-stuffs, is sufficient to establish in every case the identity of certain bacteria. To enable us to do so, we must practice Koch's pure-culture method. From the soil in which the various micro-organisms taken from the diseased tissue were allowed to mature, the one bacterium is removed which we wish specially to examine. Under the strictest aseptic precautions, taking care that no other microbe present in the atmosphere may be accidentally mixed with the micro-organisms under investigation, the special bacterium is carried to a soil which seems specially adapted to its development, a fact which has often first to be determined by a long series of observations. Upon this soil the behavior of the microbe is studied, and experience has shown that every pathogenic bacterium develops in a different manner, but each species always in the same. After from two days to three weeks—thus greatly varies the time in the different species—there appears at the point of the soil where the bacteria had been deposited, a small elevation or depression, either of the shape of a circle, or of a star, or of some other form. Around some of them the soil is dissolved and has become fluid: others present the appearance of dry scales, and their environs are dry. Not two species of bacteria develop alike. Remember that they all probably belong to the vegetable kingdom; they are plants, and behave as such.

From this short description you will have obtained some idea of the difficulties which have to be overcome in the searching after a special pathogenic micro-organism.

When Koch arrived in Egypt, he and his assistants at once commenced to make post-mortem examinations of the bodies of cholera patients. But notwithstanding the most careful dissections and microscopical examinations, neither in the blood nor in the tissues of these bodies was any specific micro-organism detected. Koch then examined the discharges and the contents of the bowels of cholera patients. There he thought to discover what he was looking for. Certain bacteria, which his experienced eye at once recognized as a species characterized by a form and behavior differing from those of any known to him, always reappeared in the contents of the bowels and the discharges of cholera patients; and the more recent the case, *i. e.*, the more rapidly death had taken place, the more numerous were these bacilli, and the less were they accompanied by other micro-organisms.

But it was not until Koch had arrived at Calcutta that he found an opportunity to dissect several bodies of patients who had died within one hour after having been seized by the first symptoms of cholera. In these cases, the contents of the intestines showed the same characteristic bacteria in their pure culture and in enormous quantities.

Koch at once began the necessary bacteriological investigations. In consequence of their peculiar form, greatly resembling a comma, he gave them the name of comma-bacilli. When subjected to the process of artificial pure-culture, he soon discovered that the comma-bacilli behaved in a manner utterly at variance from that of any other known species of bacteria. At the place of deposit there first appears a grayish speck of the size of a pin's head; under favorable conditions this happens within forty-eight hours. Then the gelatine surrounding this spot becomes completely fluid and a depression shows itself, which has somewhat the form of a funnel, and extends deeply into the gelatine. This peculiar behavior

has not yet been observed in any other species. Koch then endeavored to determine other conditions for its existence, and he found that the comma-bacillus, if deprived of moisture for several hours, loses its vitality, though it may regain its power of reproduction, if then once more exposed to influences favoring its multiplication. But if the bacillus was kept without moisture for a period of twenty-four hours, it was destroyed forever and never again obtained its power of reproduction. His experiments, a description of the details of which could occupy hours, further proved to Koch that the comma-bacillus of cholera did not have a permanent existence—a Dauer-Zustand—which fact, taken together with the inability of this bacillus to live without moisture, explain to us an observation which was made before the discovery of the comma-bacillus. Cholera, when it has broken out in any locality, rages there for a certain time, but if once the epidemic has ceased, it will not reappear in the same district without its having been re-introduced. For instance, small-pox, if epidemic one winter in a city, may have apparently ceased, and none of the inhabitants may fall a victim to it during the following summer. But in the ensuing winter it may once more break out with a vehemency even greater than at first. Such is never the case with cholera; after it has once abandoned a locality the region cannot again become infected except by another epidemic of the same disease. This fact is now explained by Koch's great discovery; the bacillus having no permanent, only a transient existence, its germs cannot lie concealed in the ground or out-of-the-way places to regain their vitality under recurring favorable conditions; having once ceased its manifestations, it does so forever.

Another behavior of the comma-bacillus has still more importance. It can exist only in the intestinal canal, and here only in the small and large bowel. It can only be swallowed, and not inhaled. This is the reason why we never have any lung complications in this disease, and why there is no danger of infection by the atmosphere. The bacillus attaches itself and keeps its vitality only where there is moisture. It is not propagated by the air, in which it could not exist. This explains to us the fact that the disease has always wandered from place to place with the slowness, or rapidity, if you will, of human intercourse. Certainly, the burning of fires, the disinfection of the air, and the exclusion of dry articles of commerce coming from an infected district, are all based upon erroneous suppositions.

The most important fact elicited by Koch was the action of acids upon the comma-bacillus. Koch found that this pathogenic microbe could not live in any fluid of an acid character, and that the stronger the acid the more dangerous it is to the existence of the morbid agent of cholera. In consequence of this indeed important discovery, Koch demonstrated that the comma-bacillus could not pass alive through the *healthy* human stomach. Investigating the mortality records and the reports sent to him from physicians that had enjoyed a great experience in cholera-epidemics, Koch found that not a single individual in possession of a healthy stomach had ever been attacked by cholera; but persons suffering from defective digestion, either in consequence of their having passed through such diseases as typhoid fever, or on account of a chronic malady, or because of an error in diet, were invariably the victims of Asiatic cholera. There is still another fact confirming the truth of these observations. It had long attracted the attentions of statistics, that especially in large European cities infected by the epidemic the greatest number of deaths from this disease always happened on Mondays, and amongst the lowest class of people. If we remember that these people in Europe usually commit their worst excesses in eating and drinking on Sundays, so that the Monday attack of indigestion has become almost proverbial amongst them, we cannot wonder that the most virulent cases of Asiatic cholera should happen on that day. For the normal secretion of the stomach, the gastric juice is the only one of the digestive fluids having an acid character, and the comma-bacillus cannot exist and pass alive through the healthy organ. It matures and multiplies in the intestines, but to do so it must reach the bowels in a live condition, and as it can penetrate thither only by way of the stomach, if this secrete the normal acid juice, the comma-bacillus will receive its death-blow in that same fluid. Should, however, from some diseased condition this gastric juice have lost its acid, germicide character, then the morbid agent of cholera will pass on without any impairment of its vitality, to the regions specially favoring its development.

One other fact proves the correctness of this theory. In the last London cholera epidemic the city was divided into small districts, in each of which a dispensary in charge of an able medical staff attended to the cholera patients. By an accident it was discovered that sulphuric acid, if administered in diluted state in the prodromic stage of cholera-diarrhœa, not only at once put a stop to the diarrhœa, but also protected the indi-

vidual against the outbreak of the graver disease. What had then been determined by empirical observations Koch gave a scientific basis, and we can now see the reason of the beneficial action of sulphuric acid. In persons with a perfectly healthy stomach the comma-bacilli, though they may be and probably are often swallowed with the food we eat and the water we drink, are at once killed on entering the main organ of digestion, and they thus give rise to no disease. In individuals where either the quantity of the swallowed bacilli is too great, or what is far more probable, where in consequence of an error in diet or of some slight morbid condition, the secretion of the gastric juice is sufficiently interfered with, not to be able totally to destroy the bacilli, but not sufficiently to allow them to escape totally unhurt, the micro-organisms have lost some of their vitality, and therefore give rise to the disease in a milder degree, and are then easily acted upon by remedial agents, though if left alone they may gradually regain their normal vitality, and then ultimately produce the most alarming symptoms. Only thus can we explain those cases where the epidemic disease first begins with a rather mild diarrhœa, and later assumes the gravest aspect, if the diarrhœa be not early attended to. On the other hand, in persons whose disturbed condition of the stomach makes the gastric juice inert as far as its influence upon the comma-bacilli is concerned, these microbes reach the intestines in their full vitality, and thus developing without impediment, under circumstances most favorable to them, they give rise to Asiatic cholera in its most virulent form.

Lastly, we also now have an explanation of the fact that the epidemic disease causes the greatest ravages amongst the poorer classes, and in the most neglected districts of large cities. Such people, who are in the habit of eating unripe fruit, who enjoy a warm meal but once a week, if that often, who generally drown their misery in the worst kinds of alcoholic stimulants, who do not care whether the meat they eat has an unsavory odor, or whether the vegetables they swallow are partially decayed—such people, I say, mostly suffer from a disordered state of digestion, their gastric juice is wanting in quantity and deficient in quality, and thus the comma-bacilli pass unharmed through that organ whose normal secretion in the healthy state is the most efficient barrier to the destructive influence of the morbid agent.

It was formerly thought, and is still thought to-day by those not knowing better, that the filthy condition of the houses, and especially of the water-closets, was mainly responsible for the greater number of victims of cholera in such localities. But not only do the facts regarding the state of digestion of these people, and the kind of food they use, fully explain the predilection of the disease for them, an observation of Koch directly proves that the filthy condition has very little to do with cholera. Koch noticed that the bacteria of putrefaction and decay are natural enemies of the comma-bacilli. Wherever these are collected in large numbers and in full activity, they soon lose their vitality and finally die, if septic bacteria become added to them. Koch has demonstrated this fact even in the bodies of cholera patients. Whenever the comma-bacilli pass unharmed and in large numbers through the stomach and reach the intestines, they seem to develop like other pathogenic bacteria a special poison, which like the ptomaines at once overwhelms the human organism and thus cause death within an hour, under the symptoms of the most profound intoxication. At the post-mortem of persons that have died thus suddenly of cholera, the bowels are filled with innumerable masses of comma-bacilli in their pure culture, without the admixture of other bacteria; and if one drop of the fluid surrounding them is injected into the circulation of an animal, this dies at once under the symptoms of deep intoxication.

If death does not take place thus rapidly the mucous membrane of the intestines becomes inflamed, and in this tissue and in that of the tissue beneath and that surrounding the solitary glands and Peyer's patches the comma-bacilli are met with in every stage of development. But if life is still more prolonged, so that death sets in at the end of a week, the tissue hitherto inflamed appears mortified. Deprived of its nutrition, as the places surrounding the capillary vessels are so filled with comma-bacilli that they compress the blood-vessels and cut off the supply, the tissues decay, and at once another species of bacteria, the so-called septic, or bacteria of putrefaction, show themselves.

Henceforth the further progress has been studied from day to day by post-mortem examinations of bodies, where the patients died on the seventh, eighth, ninth or tenth day, and so on. Here Koch made the important discovery, that day by day the septic bacteria increased in numbers, and encroached more and more upon the comma-bacilli, which finally were overwhelmed, as it were, and suffocated by the superior numbers of the septic bacteria, until finally comma-bacilli were met

with no longer. There were cases where the symptoms of cholera had ceased and yielded to those of a low typhoid condition—a septic fever.

While these observations thus explain the symptoms observed in the disease, they have led to another far-reaching conclusion. The discharges of cholera patients are usually emptied into water-closets, where decay and putrefaction are continually and actively carried on by septic bacteria. Left to themselves the comma-bacilli present in these discharges and contained in the water-closets, are soon overpowered and destroyed by the septic bacteria. It is at least doubtful, therefore, whether the disinfection of water-closets, as usually practiced, will not tend to favor the propagation of the comma-bacilli rather than to destroy them. In Toulon, and recently in Paris, observations of this character have been made. When the disease broke out in these cities, and as usual attacked mainly the poorer classes, the most active disinfection was practiced by the authorities in these localities. But not a little were they amazed when they discovered that the disease seemed to appear with renewed energy, and increased its virulence rather than diminished it. While we, therefore, should take care to prevent the accumulation of filth and similar moist material in the streets and houses, as the comma-bacilli develop best where there is moisture, we should not be too hasty in our efforts of disinfection, especially as regards the places into which the discharges of cholera patients are dumped.

While Koch was in Egypt and Calcutta, he made two observations, which explain the manner in which the Asiatic cholera is often propagated, and which, at the same time, prove the correctness of Koch's theory, as they really amount to self-inoculation. In a village in Egypt, some eight miles distant from the nearest infected place, and thus far free from cholera, one day the epidemic broke out, and in about thirty families many a one fell a victim to the disease. A careful investigation was started, and it was discovered that the members of these families had all been drinking water from a certain brook. Two days before the outbreak of cholera in the village a washerwoman had brought from the neighboring infected city a large amount of linen of cholera patients, and washed the same in that very brook.

In a southeastern direction from Calcutta, where then cholera raged, several villages were situated, in which no case of cholera happened until one day, in the village the most central of the others, about 200 individuals were suddenly taken sick with the disease, and died. There, also, careful investigations were made, and it was discovered that all those persons had been supplied with water from one special tank. It leaked out that several women who had received the linen of cholera-patients from Calcutta to have it washed, had thrown this linen into the tank and there washed it.

In both cases, the water—in the one, that of the brook, and in the other, that of the tank—was examined microscopically. Any small organic substances, as small splinters of wood, etc., taken from these two waters were found to be literally covered with innumerable comma-bacilli in the most perfect state of pure-culture.

Koch, on examining soiled places of cholera linen, invariably discovered in them living comma-bacilli as long as the soiled places were moist; but whenever such a place had been completely dry for twenty-four hours, all the bacilli were dead. The same was the case with the discharges of cholera-patients.

I have thus far tried to prove to you that the comma-bacillus is a species of its own kind, possessing certain characteristic peculiarities not owned by others of the same genus, and that these peculiarities coincide with what we know of those of the morbid agents and the manifestations of cholera. Notwithstanding the facts and observations quoted would alone be sufficient to prove these bacilli the pathogenic element of the Asiatic disease, I have yet to mention two others ere the actual scientific proof may be said to be clearly established.

It must be demonstrated that the comma-bacillus is not met with in any other infectious disease. Koch, with all his experience, says that he has never found it except in cholera. But, a a few months ago, two German observers thought they had discovered the same bacillus in the disease known as cholera morbus. I have received Koch's reply, which he published a few weeks ago in one of the best German medical papers, and which has not yet appeared on our side of the Atlantic. In this reply Koch proves that the two anthors were not acquainted even with the rudimentary knowledge necessary for these investigations; and he then shows that the bacillus which they detected, and which they considered the same as the comma-bacillus, is a totally different variety, and was not even contained in the discharges which they procured from their patients, but was an accidental admixture from the atmosphere, the two authors not having employed the necessary precautions to exclude such an oc-

currence. As this was the only case where the comma-bacilli were said to have been found present in another disease, we may take it for granted that they are met with only in Asiatic cholera.

But the final proof is the direct infection. For a long time Koch did not succeed in producing genuine cholera in animals by injecting comma-bacilli into their circulation. He explained this failure by the well-known fact that there are some diseases which affect only the human being, and cannot be communicated to the lower animals. Had he but thought of his own discoveries, he would himself have tried the experiment in a different manner, and obtained success. You will remember that Koch never found the comma-bacilli in the blood or in any other organ but the intestines of cholera patients, and that he himself proved that the comma-bacillus cannot pass the healthy stomach. It was, therefore, to be foreseen that the introduction of the comma-bacilli into the circulation of animals would not produce the symptoms of cholera, as this micro-organism does not develop in the blood. Neither could any result be expected from swallowing. All animals that, like the human being, have a stomach prepared to digest alike meat and vegetable food, usually enjoy a very healthy stomach, as they do not expose it to the same rough treatment that human beings are apt to subject their main organ of digestion to.

Professors Rietsch and Nicati ultimately succeeded, during the Marseilles epidemic, in producing in animals the characteristic symptoms of cholera, by injecting the comma-bacilli which had been obtained by artificial pure-culture into the duodenum, that is, the upper part of the small intestines, so that the bacilli had not to pass through the stomach. I have received from Koch the latest and most direct information a few days ago, that these experiments were repeated in the German Imperial Board of Health. Dogs and guinea-pigs were employed for this purpose. Koch first artificially developed the bacilli by pure-culture. He then so diluted the fluid of the pure-culture that he obtained the one-hundredth part of a drop of it, and this minute quantity he injected into the duodenum of a large number of animals. They all died within from one-and-a-half to three days under all the symptoms of Asiatic cholera. Their post-mortem examination revealed exactly the same condition of the intestinal canal that is met with in human bodies of patients who died the second or third day from the disease, and in the intestines were found innumerable quantities of comma-bacilli in the state of pure culture. Considering the smallness of the dose employed, and the fact that death set in two or three days later, the possibility of poisoning is excluded.

The final proof that the comma-bacilli are really the causing element of Asiatic cholera has therefore been adduced. It might interest you to know that the foremost of America's physicians, Prof. Austin Flint, in New York, has also declared himself convinced of the truth of the discovery.

At last medical science is in the condition to become the real benefactress of the human race. It would lead me too far to-night were I to mention all the possible consequences, all the probable results, all that we can learn from this discovery. I may do so with your permission at some future time. But that you may know how to visit with safety cholera patients, and to live amongst them, let me tell you what the king of Italy did. While the disease was at its height in Naples, he arrived from Rome and visited the cholera hospitals in Naples. He escaped uninfected, but why? All his food, and all the water and wine he drank, were sent to him from Rome in sealed and hermetically closed bottles and boxes. As he could not become infected by way of inhalation, but only by the food and water swallowed, care was simply taken to have the food and drink pure, free from comma-bacilli. Should the cholera visit us, have your main organ of digestion in the best possible order, avoid errors in diet, live on the plainest food, and have every drop of water you drink, every particle of food you take, thoroughly boiled, and you will escape all danger from infection. And, if notwithstanding these precautions, living comma-bacilli reach your intestines, and indicate their presence by the first symptom of the mildest diarrhœa, at once have recourse to your physician, and putting yourselves under his care, minutely follow his directions, and the once-dreaded disease will soon become a matter of little concern to you personally.

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER, M. D.

Reported by W. H. Seelye, A. M., M. D.

Convulsions.

The first patient shown to the class was a man of about 35 years of age, well-built, muscular, and healthy in appearance, who had been picked up in the streets and brought to the hospital less than half an hour before. He had been in an unconscious condition ever since, and as no one knew anything about him no history could be ob-

tained. He had continued to exhibit, since his admission, the phenomena which were now observed by the class. Immediately upon our entrance into the room where he was lying upon a bed, he went into a convulsion. First, there was a tonic spasm of all the muscles of the body, beginning with the face and then extending to the right arm and leg, and then becoming general. The legs were first drawn up as far as possible, and then were straightened out again, and the same was true of the arms: and it seemed, therefore, that the spasm invaded the flexor muscles a little sooner than the extensors. But after a moment all the muscles of both classes were in a state of rigid contraction, the extensors and pronators of the forearm, however, more than overcoming their antagonists. The diaphragm and the other muscles of respiration were fixed, and breathing was temporarily suspended, and the face was flushed, and the vessels congested and prominent. The pupils were in a semi-dilated condition. After this state of things had continued for twenty or thirty seconds, the rigid contraction of the muscles gradually relaxed, and a clonic spasm began which grew steadily more and more violent, the arms and legs being thrown wildly about, and all the muscles being in a state of convulsion. And now the respiratory muscles were put into a rapid action, and consequently there was loud, stertorous, and gurgling breathing, with violent movements of the chest. This condition of affairs lasted about two minutes, and the spasm gradually lessened, and then as the muscles were relaxing the urine was passed involuntarily. The pupils were now examined and found to be more contracted than they were during the spasm. The patient had scarcely become quiet after this attack, when a second one began, with a very severe and long-continued tonic spasm. In this one opisthotonos was a marked feature, the patient resting for several seconds only upon the shoulders and heels. As this tonic spasm subsided it was not succeeded by any marked clonic convulsion as in the first attack. So he went on for over half an hour, having one spasm after another, some tonic and others clonic, irregularly, repeated every two or three minutes. During these attacks the pulse was very rapid and the respirations deep and violent, and on one occasion, just as he was entering upon a convulsion, he uttered a loud groan resembling the "epileptic cry." He did not foam at the mouth, but the loud gurgling noise made during the violent respirations proved that there was a profuse mucous secretion in the respiratory passages. That he had bitten his tongue in some of the earlier attacks was evident from the fact that the parts about his mouth were bloody; but the possibility of this accident being repeated was prevented by placing a gag between his teeth.

Gentlemen, you observe here all the symptoms of a violent epileptiform seizure. There is complete convulsion of all the muscles, beginning with a tonic spasm and ending in a clonic spasm; and the pupils, which were dilated during the spasm, contract as it passes off. The involuntary passing of the urine is also a frequent phenomenon after an epileptic seizure. And you notice here that the water is clear and light-colored, and not unfrequently after the attack there is found to be albuminuria. But before you came in his urine was drawn off by a catheter and examined, and it was not found to contain albumen. You observe here that his urethra opens on the under side of the glans. This is a congenital defect sometimes met with, and is called hypospadias.

Now the question arises as to what is the cause of these spasms. I think we may exclude epilepsy pure and simple, inasmuch as in epilepsy the patient is not subject to such frequent repetitions of the convulsions. The convulsions may be very violent, and two or three may occur in succession; but usually after such a discharge of nervous force the patient remains quiet and in profound coma for several hours. But these convulsions would seem to depend upon some cause that is constantly acting. If we exclude epilepsy, uræmia and apoplexy suggest themselves. I told you that the urine has been examined and that no albumen was found in it. This would tend to exclude uræmia as a possible cause; for I think that in the great majority of cases of uræmic convulsions you will find albumen in the urine. But you may get albumen in the urine without its necessarily indicating any kidney disorder. Perhaps the best way of distinguishing between uræmic convulsions and those dependent upon some cerebral lesion is by means of the eye. If they are due to apoplexy, with an effusion of blood upon only one side of the brain, you are apt to have some irregularity of the pupils, while in uræmic convulsions this is not the case. During a uræmic convulsion the pupils are dilated at first and afterwards they become contracted. So if the pupils are symmetrical, the chances are that there is no lesion of the brain with an extravasation of blood upon one side. But in case there is an extravasation pressing equally upon both sides, this rule will not hold good. But if you get a permanent irregularity in the pupils and an irregularity in the movement of the eyes, then you have good grounds for supposing that you have to deal with an extravasation.

Now, this patient is a pretty young man for apoplexy, and his arteries, so far as I can ascertain, are normal in condition, and his pulse is not hard and firm, but is soft and natural. And you may remember that I have told you that apoplexy is apt to occur in people in whom there exists diseased arteries, together with an enlarged heart and granular atrophy of the kidneys. But I do not find any cardiac murmur or enlarged heart here. I think, then, that we may fairly say that the conditions which usually accompany apoplexy being absent, this is not a case of apoplexy, or else if it is, the hemorrhage is so equally distributed on both sides, or is in such a locality as not to act upon the pupils.

But then the absence of albumen in the urine is against the supposition that uræmia is the cause of the convulsions. For in all the cases of uræmic convulsions which I have seen the urine has been albuminous. It is possible, however, that we have here to deal with a case of convulsions produced by alcoholism. But we only come to this result by a process of exclusion. Violent convulsions are apt to occur in persons given to the use of alcohol in excess. There is no odor of alcohol in this man's breath, however.

Now, what are you to do in such a case as this

when you are in doubt as to the nature of the convulsions? This is one of the most puzzling and difficult questions. If he is suffering from the effects of an apoplexy, there is nothing which you can do to relieve the patient. For even though you were to bleed him, you would not be doing him any permanent good. But if the convulsions proceed from uræmia, then you have several courses before you. Undoubtedly, the most prompt and efficient means of relief is by blood-letting; though diaphoresis, catharsis, and diuresis, may also be employed to relieve the system of the poison. But these latter means are too slow to employ under such circumstances as are presented here, where the urgency of the case demands immediate measures for relief. In alcoholic convulsions, however, it is, as a rule, not best to bleed the patient, unless the case is complicated with diseased kidneys. But brisk purgation and diuresis are the best means of relieving the circulation of the alcoholic poison which gives rise to them. Now, I cannot say what is the cause of the convulsions in this case; but as I watch it, I am much impressed with the number and violence of them, and this leads me to think that they may be uræmic. So believing that they are dependent upon uræmia, even in spite of the absence of albumen from the urine, I am disposed to resort to venesection as a means of relieving him. So Dr. K. will now perform this operation and we will watch the results.

Operation.—A few turns of a roller bandage were first wound around the arm above the elbow so as to obstruct the venous circulation, and thus render the superficial veins prominent; and then with a scalpel an opening was made into the median vein of the forearm, just below the bend of the elbow, by a single longitudinal incision nearly half an inch long. The blood came away slowly and irregularly, sometimes stopping completely, because the skin had not been cut by the incision directly over the opening in the vein, so the blood coagulated between the vein and the skin, and thus stopped the flow. In this way about eight ounces of blood were taken, and it seemed to lessen the frequency and violence of the spasms at once. And in a few minutes more the patient began to make semi-voluntary movements, such as scratching the buttocks and thigh, which were already scarred with old scratch-marks, and he seemed to be very restless, throwing his arms and legs about. But the true spasms had apparently nearly ceased. The bleeding was checked by pressure over the wound in the arm, and by bandaging it from the wrist to the elbow.

In the case of a colored woman who was brought to the hospital the other day under just such circumstances, blood-letting was resorted to, in the hopes that the convulsions were dependent upon uræmic poisoning. But she died soon after, and the autopsy showed that the cause was really a meningeal hemorrhage. This shows you that the difficulty of making a diagnosis in these cases is sometimes very great, and how easy it is to make an error. But we are justified, I think, in trying to relieve these patients, even though we are in doubt as to the cause of the evil. As to the quantity of blood which should be taken, it is not possible to give any definite rule. You are safe in drawing off from eight to twelve ounces, and I think that if you do not got any relief from the removal of twelve ounces, you are not likely to by taking more; for this is enough to relieve the high pressure of the blood and to diminish the violence of irritation produced by the uræmia. About eight ounces of blood has now been taken away from this patient, and I think it has diminished the heart's action somewhat; for whereas the pulse was very rapid before, it is now very regular, and beats only one hundred and sixteen per minute. There is still some tendency to convulsion about the muscles of the jaws and wrists, but there are no longer any large convulsive movements. As I hold his wrist I can feel every now and then a slight spasm of the tendons of the flexor muscles of the hand. Sometimes under the influence of blood-letting the effect is very marked in restoring the patient at once to consciousness, as well as in promptly relieving the convulsions.

You see now, gentlemen, that the patient is becoming very restless, but these movements are not at all of the same character as those which you saw a short time ago. But they are irregular and semi-voluntary, and such as are not unfrequently observed in patients after an attack of convulsions. To quiet this restlessness I would suggest a small hypodermic injection of morphia. This is itself a remedy which is sometimes used in convulsions, and it has been employed especially in puerperal convulsions. It acts as do chloroform and ether, by allaying the irritability of the nerve centres, upon which the convulsions depend.

Myelitis.

The next patient, F. W., is a widower, 54 years of age, a native of Ireland, and has no occupation. Was admitted December 21. Gives no family history. Has always enjoyed good health, and has never had rheumatism or malarial fever. Does not drink malt liquors, but for the past few years he has been accustomed to take three or four glasses of whisky a day. For the last five or six years he has suffered more or less from chronic bronchitis, which is always more troublesome in the winter time. A little over a year and a half ago he contracted a chancre, which was followed by a secondary roseola and a swelling of the inguinal glands without suppuration. And last winter he suffered from a kerato-iritis in both eyes. He was put upon the mixed treatment with mercury and iodide of potassium, and the dose of the latter was gradually increased from ten to thirty grains, which caused vomiting. He has now a slightly-marked squamous syphilide on both of his legs. For the past few months he has been troubled with biliousness and constipation. On the 14th of December he was exposed to the rain and cold, and after he got home he had a chill, which was followed by feverishness and a sweat at night. The next day he found that he could not pass his water; so the following day he had a large quantity drawn off by a catheter. At that time he had no pains in the back or legs. The day before he was exposed he took a cathartic composed of senna and manna, which was followed by a violent movement from the bowels; but he has had none since. On Saturday, the 17th, he observed that his left foot and ankle felt numb, and soon after he found that he could not

move that leg; and sometimes it would feel alternately cold and hot, and he would have creeping and pricking sensations in it. Two days after, the same sensations began to appear in the right foot and leg; and they have been gradually creeping up both limbs, until now the boundary line of perverted or lost sensibility is at the level of the umbilicus. Of late he has noticed a sense of constriction across the back. He has passed no urine naturally since the first day of the attack. The left pupil has been permanently dilated or enlarged since the attack of kerato-iritis. He has no headache. Two or three days ago his bronchial cough became very troublesome again. There is now complete loss of power in both lower extremities. On admission his pulse was 98, respirations 20, and temperature 101.2°. His urine is light-colored, and contains a small amount of pus.

Gentlemen, the history of this case, with its attending circumstances, enables you to judge pretty clearly as to the nature of his malady. There is loss of motion in the lower limbs and diminished sensibility, and there are also some subjective sensations of numbness and formication, and an inability to pass urine, and obstinate constipation. The loss of sensation extends upwards to about a line drawn through the umbilicus, but the limit is a little lower down on the right side of the abdomen than on the left, and while the anæsthesia is pretty complete in the left thigh, yet he can feel a little on the right, and the reflex on the right is better preserved than on the left. There is no paralysis of the sphincter ani, but there is a loss of propulsive power in the intestines, which causes the constipation. Now, what have we to deal with here? It might possibly be a congestion of the spinal cord; but in congestion you would not be apt to get such complete loss of power. Or pressure of a tumor upon the cord might cause these symptoms; but they would then have been more gradual in making their appearance. So the true cause is probably some form of myelitis. But whether it is a transverse myelitis, or one which mainly involves the anterior horns of gray matter, is a question, and it is a question which I think cannot yet be positively answered. But the manner in which this attack appeared is very characteristic of the commencement of a polio-myelits of the anterior horns of gray matter. For in this disease there is usually a history of exposure or fatigue, and then a chill, and fever, and disturbances of sensation, and of muscular action, and not infrequently loss of the power of urinating. The disturbances of sensation and loss of vesical power are, however, temporary in myelitis of the anterior horns. But in transverse myelitis, the loss of power and of sensation becomes more and more marked, and there are finally trophic disturbances and defective nutrition in the paralyzed parts, especially of the skin and the muscular coats of the bladder. The interesting point here is that the lesion seems to have begun upon one side of the cord, and then to have travelled over to the other, thus involving both limbs in the paralysis. Now, it is true it is rather early to get trophic disturbances, if this is a transverse myelitis; yet inasmuch as they are absent now, I am inclined to think that the lesion will turn out to be one of the anterior horns, and not one involving the whole of the cord. And other reasons for my not thinking it to be a transverse myelitis are, that there are no pains at night, such as are usually complained of, and no cramps at night, and no cincture sensation about the waist, while there is a partial restoration of the sensibility of the skin. All these considerations lead me to think that the lesion is for the most part confined to the anterior horns. We shall see.

Uræmia.

The next patient is Mrs, A. B., 58 years of age, born in the United States, a widow, and employed as a governess. She came to the city day before yesterday, and went to a strange boarding-house. Nothing more was seen of her until she was found comatose lying upon the lounge in her room, and she seemed to have remained in this condition for ten or twelve hours. An empty laudanum bottle was also found in the room. At 7:30 last evening she was brought to the hospital. There had been incontinence of urine while she was lying upon the lounge. Her son-in-law says that she had been ailing for some time, and she had just come to the city for treatment. This is all he knows about her. On admission, her respirations were 24, pulse 103, and temperature 99.8°. As to her physical condition, the pulse was increased in frequency, and there was œdema of the legs and ankles, and some degree of general anasarca. She was in a comatose condition, but there was no paralysis of the muscles. And there were no reflex movements except about the face. The pupils were narrower than normal, and they responded slowly to light. The respirations were shallow but regular. The pulse was full, slow, regular, and firm, when she was found. That there had been a convulsion was shown by the presence of froth about the mouth, but she had not bitten her tongue. Sensation was abolished. A spot of old ecchymosis was found just above the mons veneris and another upon the left tibia. There was a swelling and deformity of the phalangeal articulations. The urine as drawn by a catheter had a specific gravity of 1011, and one-fifth part of it was albumen, and it contained granular and epithelial casts. Yesterday a purge af castor oil and elaterium was administered, and in the evening she was given a hot-air bath to induce perspiration. Later on she had an epileptiform convulsion, with opisthotonos, which lasted about thirty seconds. Then succeeded a state of coma, in which the respirations grew gradually slower and slower, and they almost ceased. At 11 p. m. she became slightly aroused from the coma. Her temperature was then 103.4°. The hot-air bath was renewed, and she continued to sweat. At 12 o'clock midnight the temperature was 103.2°, and at 1:45 it was still 103.2°, and this morning at 6 o'clock it was 101°, and at 9 a. m. the pulse was 102, respiration 28, and temperature 101.2°. At 11 a. m. the dose of $\frac{4}{10}$ gr. of elaterium was repeated. She could then speak a little, but only just enough to say that her name was Ann. Whisky was also administered, and she was cupped over the kidneys. There was also considerable œdema of the lungs, for the relief of which she was cupped. Digitalis was also given, and the urine was again drawn off. The treatment has had but little effect, and

the œdema and the unconsciousness have continued up to the present time.

Gentlemen, here is another case in which, like that of the man man you saw first, the question arises as to the cause of the convulsions and coma. The history here enables you to arrive at a more definite and positive conclusion than in that case. From this we learn that she was in feeble health before, and she came to the city to consult a physician, and then she was found comatose in her room, with the evidences of having had a convulsion, in the froth about the mouth and the involuntary emptying of the bladder. After she was brought to the hospital she had another convulsion, and she has remained in a more or less complete state of coma ever since. There are no signs of any local paralysis, and she moves both sides of the body equally well. There is no facial paralysis, and no difference in the two pupils. They were contracted when she first came in, and were but slightly sensitive to light. But she responded to the test which we have lately used here, and which has proved of some value for diagnosing uræmic from alcoholic coma. That is, by suddenly slapping the patient's face with your hand, there will be some reflex movement in the irides. Besides, the urine was found to be highly albuminous and to contain casts, and this showed the existence of a structural disease of the kidneys. Hence, the diagnosis was comparatively easy. This is not the history of any other than a uræmic coma. But upon examining the patient objectively, we get some further interesting facts. For her hands show evidences of an arthritis in the phalangeal joints, and some also in the tempero-maxillary articulation, and there are some hard deposits in the ears. And I doubt not we would find the same conditions in other joints of the body if we were to examine them. There is complete ankylosis of one elbow, showing that she has for some time been the subject of a gouty arthritis, and it is not improbable that she has gouty or granular kidneys.

Now, you might ask whether in all cases of uræmic coma I would resort to the same measure as I did in the case of the man you saw first. I think not. And I do not think there would be any expediency in doing this here; for you must bear in mind the age and strength of the patient. He is a young man and can well bear the loss of blood, but I would hesitate before bleeding an old and feeble and anæmic emaciated patient. Here resort has been had to the safer method of depuration by means of a purgative of castor oil and elaterium. But there has failed to be any response to this treatment, as is not unfrequently the case. This may be due in part to the insusceptibility of the patient to the medicine, or in the case of the elaterium it may be due to the worthlessness of the drug, different samples of which vary much in power. She was also put in a hot-air bath in order to induce sweating. But there was very little response to this, too. It is probable that no medication will do any good here. Her age is against her, and she has probably a degenerated heart, and altogether she is in no condition to recover from such a severe shock to the nervous system. The œdema which occurred two or three hours ago is not an infrequent occurrence, and it is often the precursor and the immediate cause of death.

Medical Societies.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

Thursday evening, January 8, 1885. The President, Dr. Shakespeare, in the chair.

Primary Tumor of the Liver in a Child Nine Months Old.

Presented by Dr. E. O. Shakespeare.

Aortic Valvular Disease, with Rupture of One of the Leaflets.

Presented by Dr. Shakespeare.

Malignant Tumor of the Kidney.

Presented by Dr. Shakespeare.

A Large Renal Cyst.

Presented by Dr. Shakespeare.

[The notes of the above cases have been withheld for future publication, and in consequence, the interesting discussion upon them, in conjunction with the case presented by Dr. Longstreth, must also for the present remain unpublished.—Recorder.]

Sarcoma of the Clavicle.

Presented by Dr. G. E. de Schweinitz.

This specimen was sent to me by Dr. John Ashhurst for microscopical examination, and he kindly gives me permission to exhibit it to-night. The tumor occurred in the person of a young girl, S. L. B., aged sixteen, who came to him for treatment last August. She was a somewhat frail-looking, clear-skinned blonde, whose general health up to the time of the appearance of the growth had been satisfactory. The family history was good; none of the other five children composing the family presented any similar affection, nor was there any history of tumor for two generations back. The tumor began at the left sterno-clavicular joint, as a small, nut-shaped swelling, having arisen without known inflammatory or traumatic origin, although, as further stated, they always believed that the patient had in some way, and unknown to herself, received an injury at this point. The growth of the tumor was rapid, and at the end of five months stood out as a prominent swelling, as large as an orange, occupying the inner two-thirds of the clavicle, and was covered by somewhat reddened and thinned skin. Pain, although not constant, was at times a very severe symptom.

On the 7th of last August, Prof. Ashhurst removed the growth, together with the inner two-thirds or three-fourths of the clavicle. Examination of the gross specimen shows it to be a spindle-shaped growth, about four inches long, three inches at its greatest breadth, and two inches deep, which has taken its origin in the medullary cavity of the bone, and gradually become surrounded by a firm fibrous or periosteous capsule. The true tumor tissue is of moderate consistence and a reddish-brown color. Microscopic examination reveals the following points of interest:

The capsule is composed of dense fibrous tissue, from which prolongations pass, dividing the tumor into numerous spaces, which are filled with small round sarcoma cells. These spaces are in many places again divided by a delicate spindle-shaped tissue into small alveoli. In addition to

the round cells, spindle-shaped cells are also seen in spots; giant cells are absent, or at least only a few multi-nucleated cells, relegated to the regions of the spindle cells, are noted. The tumor, I think, should be classified as a small round-celled sarcoma, with an alveolar arrangement. If this tumor be accepted as a variety of alveolar sarcoma, it is somewhat unusual.

Twice before this evening specimens of alveolar sarcomata of the long bones have been exhibited to this Society—one of the femur, by Dr. Nancrede, and one of the knee-joint, by Dr. Formad. At that time Dr. Formad thought the variety of the sarcoma justified a rather more favorable prognosis than usual, while Dr. S. W. Gross, during the discussion, after referring to the somewhat unusual microscopical character of the tumor, thought the outlook for the patient was bad, as this variety of sarcoma is peculiarly fatal. Dr. Formad's prognosis was correct, because in that instance the patient was alive and well, if I am not mistaken, for some time after the operation, and may be now, for aught I know.

In regard to the result of the present case, I am able to speak quite definitely. Although the operation was not successful, and the removal of the growth quite complete, the hemorrhage insignificant, and the recovery of the patient satisfactory, in about two months after the operation the growth reappeared, either in the old wound or about two ribs lower. In this case, then, the truth of Dr. S. W. Gross's remarks has been only too thoroughly proved.

Dr. Shakespeare said that this specimen was of interest on account of the rarity with which similar ones had been presented to this Society. Through the kindness of Dr. de Schweinitz, he had the opportunity of examining sections from the growth, and thoroughly agreed with the exhibitor as to its nature,

Dr. Simes had also examined microscopic sections and endorsed the statements made by the preceding speaker.

Alveolar Sarcoma of the Kidney.

Presented by Dr. M. Longstreth.

The patient, J. E., æt. nine months, was first under the care of Dr. McOscar, to whom I am indebted for the specimens and this history, suffering from an attack of summer complaint. The patient was at that time three months old, and had been ill for a week or two. He was in a state of great emaciation, and upon examination of the abdomen a swelling was found in the right flank. The little patient recovered from the bowel trouble, but the general condition did not materially improve. During the remaining six months of life, the child was only occasionally under observation, and at those times suffered from paroxysms of pain apparently in connection with the tumor. The bulk of the tumor, as felt through the abdominal wall, did not seem to increase greatly up to his death. The urine was not carefully inspected. Three days before death, the pain increased to great violence, and in this condition death came. The post-mortem examination showed the enlarged right kidney more firmly adherent to the posterior abdominal wall, and to the ascending colon and mesentery, as well as portions of the small intestine attached to its anterior surface. The diseased organ weighed 52 ounces, and presented itself as a rounded, slightly oval mass, regular in outline, smooth of surface, and with a moderately firm elastic consistence. The capsular surface was of pretty dense, shining whiteness, with conspicuous small vessels passing over it. On section—which measured 3½ inches by 2 inches in the two diameters—the tissue presented a very varied appearance. In parts, it was of a dense white, perfectly homogeneous aspect; in others, the pinkish-white mass showed streaks of yellow, with numerous small spots of red, and there were also large blood-red areas. In other parts the tissue was breaking down into cysts, of which several large ones were present, the largest of the size of an English walnut. The cysts were all situated on the periphery of the mass, but they did not cause any protrusion of the capsule. At the upper extremity of the mass, there was found a portion of kidney tissue not invaded by the new formation. On section, this portion occupied about one-half inch of the long diameter of the mass, and was seen to be separated from the new growth by a thin partition of connective tissue; externally it showed itself like a lobule of kidney, fitting like a cap on the spherical tumor, as does the supra-renal capsule on the kidney itself. The microscopical examination showed the new formation to be a small round-celled sarcoma. The greater portion of all sections presented cells nearly rounded in figure, imbedded in a perfectly homogeneous basis substance. The uniform area of cells was, however, interrupted by streaks of spindle-cells running in narrow bands, enclosing greater or less areas of round-cell tissue. These circumscribing bands of spindle-cells sometimes formed circular areas looking like the cross-section of a tube; in other places the bands pursued a very tortuous course, resembling the outline of a twisting, undulating tube, cut in a longitudinal direction. The bands of spindle-cells were never of great breadth, rarely more than four or five spindles. The spindle-cells were not regularly or closely fitted, but were embedded like the round-cell elements, in a homogeneous basis substance. In the spindle-cell bands there were occasionally seen fine capillaries filled with red blood-corpuscles, which sometimes ran along for a considerable length; many other capillaries were seen cut transversely or obliquely, also in the spindle-cell tissue. Many areas of hemorrhage were visible. In many places a scanty fibrillar tissue, with various shaped nuclei, oval, angular, and spindle, was seen. This tissue was thrust in and filled the interstices between the areas of round-cells, circumscribed by the spindle-cell tissue. Thus in the section one passed from areas of round cells to the narrow bands of circumscribing spindles, and then into fibrillar tissue, with open meshes apparently without any inter-cellular basis substance. The whole picture resembled the cortical portion of the kidney, transformed by the presence of a new growth; the lumen of the convoluted tubes, greatly enlarged, were filled with a round-celled homogeneous basis substance tissue; the base-membrane of tubes transformed into spindle-cell bands, and finally areas of hyperplastic inter-tubular connective tissue, in which or along the basement membrane of the tubes

(spindle-cell bands), ran the inter-tubular capillaries. The left kidney weighed five ounces. On section it presented a normal aspect; the capsule separated easily, was not thickened, and the surface of the kidney remained smooth. The microscope showed no alteration of its tissues. The liver was large, smooth, blunt-edged, pale; under the microscope a very high degree of fatty infiltration was found. The other organs showed nothing especial to note. No secondary new formations were found.

Thursday evening, January 22, 1885. The President, Dr. Shakespeare, in the chair.

Two Cases of Nævus Pigmentosus.

Presented by G. E. de Schweinitz, M. D.

The first of these specimens is one removed from the face of a patient by Dr. John Ashhurst in the University Hospital. The man was aged about forty years, and the tumor took its origin in an ordinary mole, which under the stimulus either of external irritants or undue manipulation, grew into a slightly-raised mass, with flattened top and constricted base. After Prof. Ashhurst had excised the growth, I made a microscopical examination of it, with the following result: The uppermost portion of the tumor is densely pigmented, and the pigment is further seen to be of a brown or brownish-black color and contained in spindle or round cells, or to exist as free nuclei and granules. These pigmented spindle cells sometimes are arranged so as to form the boundaries of alveoli, which are in their turn filled with moderately-large unpigmented lymphoid cells. The base of the mass shows a small cell infiltrate, enlarged sebaceous glands, and a massing of the epithelium of the part, forming the appearances of squamous epithelioma. Below, the fat and subcutaneous tissue presents nothing abnormal. This growth my be classed, I think, as a hypertrophied mole having an epitheliomatous base.

The second specimen was removed by Dr. Agnew from the back of a man, also a patient in the University Hospital. This tumor developed from a mo.e, and grew as a papilla-shaped excrescence above the surrounding skin level. Microscopic examination of the mass showed it, like the former one, to be composed of a densely-pigmented tissue largely made up of spindle cells and free granules. Among the interstices of these were numerous blood channels filled with corpuscles. No malignant change at its base was noted, and the surrounding skin was normal. Ziegler, in his recent work on pathology, speaks of the not infrequent occurrence of melanotic and alveolar sarcoma in cellular warts and pigment spots; and certainly some parts of the specimens from the first case are strongly suggestive of a sarcomatous structure.

Urethral Polypi.

Presented by Dr. de Schweinitz.

These specimens of urethral polypi were removed from a patient with the following history: ———, aged about 30 years, contracted gonorrhœa, which was unusually stubborn and prolonged in its course. The disease had lasted about five months, when I first saw the patient. He was then suffering on account of some imprudence, from a moderately sharp attack of cystitis. Having recovered from this and from the acute symptoms of the exacerbation which had probably caused the cystitis, he returned to his former condition of a drop or two of purulent discharge in the morning, which no treatment seemed to relieve. Suspecting then that the long-standing discharge, the diminished calibre of the stream of urine, and the feeling of weight in the perineum might be due to a polypus, I explored the urethra with an improved endoscope, and found first two and later these three polypi, removed them, and had the satisfaction of seeing a cure follow this treatment. They were all situated within the first three inches of the urethra. I think no doubt these little tumors are papillomas, and belong to the more common varieties of new growths which are seen in the male urethra. A rough examination of them with a pocket lens reveals quite nicely their dendritic formation. Tumors of the urethra, in the male at least, are usually stated to be of rare occurrence; although as Wm. Belfield, of Chicago, has remarked, they may not be so rare as is usually supposed, as the urethra is seldom systematically examined upon the post-mortem table. Belfield himself, in a series of 70 autopsies, discovered two urethral tumors.

Slides from an Adeno-Fibroma of Lachrymal Gland,

presented by Dr. G. de Schweinitz.

These sections were made from a tumor of the lachrymal gland which was removed by Dr. Agnew. The growth occurred in a young man was of five years' duration, and painless, having been situated in the upper and outer part of the orbit. The eye was sightless from atrophy of the optic nerve. The tumor, which was about the size of an English walnut, was surrounded by a dense fibrous capsule; the main body of the growth was composed of fibrous tissue, through which the remains of the gland tissue are seen. The epithelium is, in places, in a state of proliferation, but apparently no formation has taken place which could be justly characterized as malignant. The tumor may be classed, I think, as a fibroma or adeno-fibroma of the lachrymal gland.

Specimens from Excision of the Astragalus for Caries, etc.,

presented by Dr. C. B. Nancrede.

Elmer ———, æt. 9½ years, had for some years suffered from characteristic symptoms of strumous disease of the astragalus, the details of which it is unnecessary to give. Early in November, 1884, he began to have chills, severe pain in the ankle-joint, which now became swollen, hectic, and profuse diarrhœa. Although I had never been able to detect dead bone by the probe, I felt convinced that an abscess, the result of carious bone, had ruptured into the previously only slightly diseased ankle-joint. I accordingly, under ether, examined the ankle-joint, which I found contained a considerable quantity of very offensive pus, which communicated with a cavity lined with carious bone, situated between the astragalus and os calcis. I excised the astragalus, and scraped out the carious external malleolus, as well as the roughened surfaces of the tibia. The boy has since done well.

Dr. M. Longstreth presented the following speci-

mens, the notes of which, with the discussion, not having been placed in the Recorder's hands as yet, will appear in print at a future time.

1. A Kidney Preserved as to Color and Texture by Ordinary Illuminating Gas. 2. Sarcoma of the Femur Removed by Amputation,

by Dr. J. H. Brinton.

Pyelonephritis and Chronic Parenchymatous Nephritis in the same Patient, Complicating Cystitis,

presented by Dr. J. Tyson.

E. D——, a prostitute, æt. 25, white, was first admitted to the Philadelphia Hospital September 10, 1883. She was at that time suffering from diarrhœa, and stated that she had previously passed blood—although appparently none was passed after admission. She had no symptoms which attracted attention to the urinary organs, and no examination of the urine was made. The history of the case at present attainable does not show whether or not she had had gonorrhœa. Her diarrhœa disappeared under treatment, but she regained strength slowly. She was discharged October 4, 1883, apparently in fair health, but was readmitted on October 25, 1883. She now presented œdema of the legs and face, and an examination of the urine made about this time disclosed the presence of pus. She complained of pain in the lumbar region and in the head, and was much debilitated. The treatment was directed to warding off a threatened uræmia. The dropsy disappeared, but her other symptoms progressively increased until death relieved her. She died with symptoms of uræmia.

Autopsy. — December 2, 1883. Nothing noteworthy in external appearance. Slight pleuritic adhesions, thoracic organs otherwise normal. Abdomen—peritoneum normal; liver normal; spleen not examined. Kidneys: left, typical large fatty organ; right, swollen to more than twice its normal size; when opened found to present a marked pyelonephritis with great distension of the pelvis, the calyces filled with pus—partly fluid and partly inspissated. Bladder was in a condition of chronic cystitis. Cause of death, pyelonephritis with large white kidney.

Dr. Tyson said that the chief interest attaching to the specimens lay in the association of these two very opposite conditions, apparent pyelonephritis, or suppurative interstitial nephritis, with chronic parenchymatous nephritis. The former condition is a well-recognized result of cystitis, the latter not. Dr. Tyson had never before met these conditions in association. Usually, as a result of a long-continued cystitis, however induced, we have a suppurative nephritis of one or both kidneys, but never, so far as he knew, suppurative nephritis. He thought the most reasonable explanation of the association was that of coincidence—that there had existed previously perhaps a parenchymatous nephritis; that upon this a cystitis had supervened, and upon this a pyelonephritis.

Dr. Tyson said that he would like to ask the members whether they had ever found association of these two varieties of diseased kidneys with cystitis. Dr. Formad thought that he had seen one such case, but there was no history. Dr. Osler said that the condition of this kidney is not infrequently met with in persons dying of intercurrent affections, and that he should not interpret the case as previous speakers had done. The kidney disease was probably of many years duration, the cystitis was secondary to it, and the other kidney affected with parenchymatous nephritis had become subsequently diseased. It was well known that the ordinary scrofulous kidney, with pus in the urine, etc., often lasts for many years, ending in general tuberculosis, or inspissation of the pus. He would like to ask how long pus had been observed in the urine, the state of the bladder, and whether there were other findings of tuberculosis in the various organs. [Owing to unavoidable circumstances, a portion of the discussion in which various explanations differing from Dr. Osler's were given, has to be omitted.—Recorder.]

Dr. Tyson replied that he was in the possession of no definite facts as to the duration of pus in the urine. The case had only been under observation for three months, and certainly pus had been detected two months before her death.

Editorial Department.

Periscope.

Malignant Disease of the Kidney—with Autopsy.

Dr. Edward T. Bruen presented the following case to the Philadelphia County Medical Society:

The specimen under consideration was removed from a man æt. 60, an inmate of the Philadelphia Hospital. The first symptom of his malady was noticed about six weeks before death. When admitted to my wards, he complained of passing pure blood from the penis, otherwise the urine was physiological. He never suffered the least pain; no dullness could be detected in the lumbar region or in the right flank. There was moderate cachexia, indicating the possibility of malignant disease, but little loss of flesh. The hæmaturia continued almost uninterruptedly until death, prior to which malignant disease was confidently anticipated. The right kidney was found to be enlarged, weighing twelve ounces—about one-half its bulk was filled with malignant new formation situated on the anterior portion of the organ. Microscopic examination by the microscopist of the hospital determined it to be an alveolar sarcoma. The tumor was rich in blood-channels, and a part of the bulk of the tumor was entirely made up of clotted blood in a semi-organized condition.

According to Zenker, Schroeder, and others, tumors of the kidney frequently do not arise from the epithelial tissues of that organ. The connec-

tive-tissue origin and character of these growths, and their richness in blood-vessels, would assign many so-called carcinomata of the kidney to the group of sarcomata.

The prominent symptom during life was hæmaturia yet in similar cases the condition of the urine is frequently absolutely negative. Ebstein (Ziemssen Cy.), states that hæmaturia occurred only twenty-four times in fifty cases. Again, authorities unite that long intervals may elapse between the periods of hemorrhage. We can easily understand this, since the cavities of the tumor which contain the blood may not communicate with the collecting tubules even in cases of extensive disease, or the secretion of urine may be vicariously assumed by the other kidney.

I have even met with cases of abscess of the kidney with only an intermittent discharge of pus. We may assume, however, that causeless and painless hemorrhage from the genito-urinary tract is a very suspicious symptom, indicating malignant disease.

Paroxysms of pain may attend the passage of clots of blood through the ureter, quite resembling those of renal calculus.

The rule ordinarily given in hæmaturia is, that blood escaping from the neck of the bladder or urethra precedes the stream of urine, and whenever blood has accumulated in the bladder in considerable quantity, blood-clots will be passed, but the urine first voided will be clear. In the case reported in this paper, pure blood was frequently passed almost unmixed with urine, so that the previously stated rules differentiating the cause of hæmaturia are of relative importance.

Paroxysmal hæmaturia can be recognized not only by its intermittent character, but by the abundance of the blood pigment, combined with the rarity of blood-corpuscles. The color of the urine in this affection is said to be due to hæmoglobin.

The hæmaturia of renal calculus can be recognized by exclusion only, unless renal colic with unilateral localized pain, or some characteristic sediment, be present; the total amount of urine may be diminished very decidedly, but not otherwise altered. Statements have been made by Heller, Moore, and others, that discharges of "floccule of cancer tissue" may be found in the urine in this class of cases. The altered epithelium of the renal pelvis and ureters has, doubtless, been mistaken for cancer cells, because although certain combinations of cellular material may excite suspicion in connection with other symptoms, nothing definite can be asserted from an examination of the urine. Recently, Dr. Julius Wolf (*Deut. Med. Wochenschrift*, September 25), has stated that iodide of potassium is much less readily eliminated by the kidney during Bright's disease than in health, and recommends the use of four or five grains daily for diagnostic purposes. Some observations by a student of the University of Pennsylvania, Mr. Gregory Guiteras, have confirmed the view—the iodine being absent in the urine in cases of disease of the kidney—but was present in abundance in the saliva. At first sight, the test might appear of service in malignant renal disease—but since malignant disease is usually a unilateral process, the test might indicate bilateral disease.

Primary malignant disease of the kidney is not always recognizable by percussion, as was illustrated by the present specimen. The bulk of the growth often projects anteriorly, since the lumbar tissues offer greater resistance. Careful percussion should be made over the lumbar and also the lateral regions; in the latter, percussion should include the space between the lower ribs and the crest of the ileum upward, or forward towards the navel. When tumors of the kidney are very large, and especially when the disease has involved adjacent viscera, the formation may become recognizable anteriorly by palpation, as well as percussion.

These growths are usually adherent to the walls of the abdomen or surrounding parts, and thus become immovable. They may be round and smooth, or nodular and lobulated, frequently giving rise to a sense of fluctuation, or elasticity, on palpation. They are, therefore, liable to be mistaken for hydatid tumors, and may be confounded with tumors of the liver. In case the growth is situated on the right side, the mistake is particularly possible, but the tumor will not rise or fall with the movements of the diaphragm, and the fingers of the hand can usually be introduced under the ribs on the right side.

These growths, when fluctuating, may indicate puncture with an aspirator as a deciding diagnostic measure, which has been practiced. In one recorded case a whitish-red mass of tissue was obtained, in which the microscope showed a delicate connective-tissue stroma, in which innumerable nuclei were imbedded, and the operation was followed by no bad results.

In renal tumors pain is a pressure symptom, and therefore may be present or absent in accordance with the size and situation of the growth. In malignant disease of the kidneys the cachexia usually noticed in such cases is a late symptom, and in cases of sarcomatous disease is never prominent. Malignant disease of the kidney is more frequent in the early and late periods of life, and is rare as a primary disease, but when present, the other kidney is usually unaffected, and it is very seldom accompanied by malignant disease of the lower urinary passages whereas malignant disease of the testicle, is often followed by renal carcinoma.

The Treatment of Acne Rosacea.

Dr. Tom Robinson thus writes in the *Brit. Med. Jour.*, January 17, 1885:

That alcohol does produce in some skins all the degrees of acne rosacea is undoubtedly true; but, to associate all cases of the disease with excessive drinking is unscientific and unfair. I know very many most rigidly careful people afflicted with the malady; and the unpopular name for these red spots being "grog-blossoms," in no way diminishes their suffering.

The treatment may be summed up in a few sentences. It is essential that all those who are afflicted with acne rosacea should abstain from all food which is difficult to digest, such as pork, veal, hashes, stews, and uncooked vegetables; and, as a general rule, from wine, beer, and spirits. The face should not be irritated by common soap, and care should be exercised as regards ex-

posure to the wind and sun. The meals should be slowly eaten at regular hours, and the fluid put into the stomach at the end of the meal.

In the first degree of the disease, it will only be necessary to prevent the development of the papules, by applying a lotion, made with bismuth and the glycerine of starch of the *Pharmacopœia*, diminishing the starch by three-fourths.

When the papules are developed, nothing answers so well as a lotion made with two grains of the bisulphuret of mercury in one ounce of almond-emulsion or glycerine of starch, used every night.

When the inflammation is acute, and suppuration is going on, we must, in the first instance, foment the face with hot water (placing a hot sponge over any troublesome spot is a simple and useful plan); and, when the acuteness of the inflammation has subsided, rub in an ointment made with twenty grains of the yellow oxide of mercury in one ounce of lard, and continue this treatment until the inflammatory process has stopped; after which, the bismuth and starch lotion answers well.

Internally, I always rely upon a mixture made with an alkaline carbonate; soda, I think, is best. If there be much inflammatory thickening, I add the solution of perchloride of mercury, or if there be any syphilitic tendency to grapple with, I add the Donovan's solution; if scrofula, cod-liver oil; but internal and external remedies are useless where organization of tissue has taken place. I have never seen an operation performed upon the advanced cases of acne rosacea.

Melanotic Sarcoma of the Rectum.

Before the Academy of Medicine, in Ireland, (*Lancet*, Jan'y 10, 1885).

Dr. Ball read a paper on a case of Melanotic Sarcoma of the rectum removed by operation. The patient, a fairly healthy-looking woman, aged sixty years, stated that eleven months before coming under observation she had noticed a pile which had been removed by operation, after which she remained free from rectal symptoms for four months. She then suffered from increased difficulty in evacuating the bowels. A slight discharge of bloody mucus appeared, and she became conscious of a hard tumor in the rectum, which partly protruded on stool. These symptoms continued to increase, and on admission defecation was difficult and painful, the pain being referred to a point immediately above the symphysis pubes. Upon examination the anus appeared normal, and the sphincter was not unduly relaxed. About an inch from the anal verge, on the anterior aspect of the rectum, two distinct and tolerably hard tumors could be felt, evidently implicating the mucous membrane: and by pressing the finger well up the superior limits of both could be readily made out, and below them a smaller mass was to be felt. The rest of the rectum appeared healthy, and no abnormal adhesion of the bowel to the other pelvic viscera was indicated. The mass was extirpated by the usual method on November 1st, a free posterior incision being made to give room. Corrosive sublimate solution, 1 to 2000, was the antiseptic used, and the wound was left open. The after-progress of the case was afebrile and satisfactory. The bowels moved for the first time on the fourth day, and the patient had complete control over the evacuations. The piece removed measured about three inches in breadth and two and a half inches in length, and consisted of the anterior two-thirds of the circumference of the bowel. There were two principal growths, separated by about half an inch of mucous membrane and equidistant from the anus. The larger had a depression in the centre, and was of a whitish color; the other was black on the surface and spherical in shape. Below the two principal tumors a smaller nodule, also black in color, was to be seen. A section carried through the two larger growths showed that the lighter colored one was of the same hue throughout, except where a small blood-clot existed in the interior; but the second was of a sooty black color, as seen on section. The shape and arrangement of cells were similar in both tumors, being those of a typical sarcoma. The cells were round, ovoid, or even spindle-shaped, with large nuclei, and in some portions resembled a form of alveolar sarcoma. In the larger one there was a very slight amount of pigment, but in the smaller pigmentation was extreme, some of the cells appearing as large masses of blackish material, while others had dark granular material, more sparsely scattered in their substance. In the portion of mucous membrane between the two growths the glands were much atrophied and surrounded with lymphoid tissue.

Nephrectomy in Infants and Children.

The *Med. News*, January 24, 1885, says editorially that at a recent meeting of the Clinical Society of London, the proceedings of which are recorded in the *Brit. Med. Jour.* for November 1, 1884, Mr. Godlee read a paper on a case of abdominal nephrectomy for sarcoma in a boy twenty-two months of age. The removal was accomplished without any difficulty; the cure was uninterrupted by a single bad symptom; and the child was discharged in six days. In six months, however, recurrence took place in the right iliac fossa; the tumor rapidly increased in size, passing down into the scrotum; and death ensued soon after.

Mr. Godlee, in his comments on the case, mentioned eight other examples of extirpation of the kidney for morbid growths in subjects of tender years. Including his own, the nine cases show that five died of the immediate results of the operation, three recovered, bnt died subsequently of a recurrence, while one was well when last heard of. Despite these unfavorable results, and in view of the hopeless condition of these patients if left alone, he argued that attempts should be made to remove neoplasms at an early stage; but, at the same time, plead against interference when the growths had attained a large volume.

Unless we greatly mistake, the weight of opinion is against nephrectomy for tumors in children, and we believe that the majority of surgeons will endorse, so far, at any rate, as sarcoma in early life is concerned, the view expressed by Mr. Henry Morris, in the fifth volume of the *International Encyclopœdia of Surgery*, which has just been issued from the press. He says: "It is probable that

future experience will exclude from the category of cases for which nephrectomy, by any method, should be done, tubercular disease, and renal sarcoma in children, as well as cancer at any period of life."

We have before us the notes of eleven extirpations of the kidney for neoplasms in children, ten being for sarcoma and one for adenoma, an analysis of which shows that the operation has thus far been of the most disappointing nature. It may be mentioned that the surgeons were Hueter, Jessop, Kocher, Czerny, Hicquet, Rawdon, Réczey, Little, Ollier, Sir Spencer Wells, and Godlee. Of the entire number, eight perished from the immediate results of the operation, thereby showing a mortality of 72.72 per cent., and three recovered, namely, the cases of Jessop, Hicquet, and Godlee. Ten of the operations were by the ventral incision, of which eight died; and one was by the lumbar incision, which recovered. Of the three recoveries, the patient of Hicquet remained well at the expiration of three months, the date of the last report; while the disease recurred, respectively, in six and nine months in the cases of Jessop and Godlee.

It will thus be seen that the immediate mortality was 72.72 per cent., and that the disease returned in 66.66 per cent. of the recoveries. In addition to this gloomy record, we have, however, to state that the operation does not prolong life, since the average duration of life was fifty days, as against an average life of between seven and eight months in the same class of subjects, when the disease is allowed to pursue its natural course.

While we are of the opinion that nephrectomy is unjustifiable in children the subjects of renal neoplasms, further experience may show that Mr. Godlee is right in asserting that interference is proper in the early stage of the affection, particularly as Kühn states that secondary growths are found in only 28 per cent. of sarcomata of persons of tender years. But when we consider that these cases rarely come under the observation of the surgeon until the tumor has attained a considerable volume, it can scarcely be expected that the future will show better results than those now recorded.

Apparent Recovery from Locomotor Ataxia.

Dr. J. L. Crawcour reports the following case in the *New Orleans Med. and Surg. Jour.*, Dec., 1884.

Mr. B., aged 45, came to see me September 11, 1883. Until about a year ago, was in moderately good health, when he first noticed some difficulty in going up stairs. He then had darting pains in the legs, which gradually became more intense. By degrees he became weaker and more unsteady.

At present, he looks pale and is somewhat thinner than usual. His walking powers are very weak, and he cannot move about without assistance. In order to go up stairs, he has to crawl on his hands and knees, and to come down he has to go backwards in a similar way, assisting himself by his hands.

He has had several bad falls. In walking, he knocks his legs about; his feet feel as if a thick piece of felt was between him and the floor, and the least fatigue rapidly exhausts him.

Any mental effort and reading produces a sense of confusion in the head, and he has occasional attacks of vertigo. The patellar tendon reflex is abolished. Asked to walk or stand with his eyes shut, he would have fallen had he not been supported.

There is some diminution of tactile sensibility in his legs, as tested by the æsthesiometer.

Passes urine more freely than natural. No albumen or sugar. Sexual desire and power much diminished. Examined by the galvanic and Faradic currents, the reactions were normal, showing that the grey matter of the cord was not involved.

The diagnosis was chronic inflammation of the posterior root-zones of the cord producing sclerosis.

The treatment which was commenced on the 11th of September, consisted in the application of the galvanic current down the spine. The anode at the second cervical vertebra, the cathode at the last lumbar. The current was derived from 35 Lechlanché elements equaling 47 gravity cells and was passed through a water rheostat, until it gave a constant deflection of the needle of a large galvanometer of 40°, including the external resistance of the body. The current (stabile) was applied for ten minutes daily.

The medicinal treatment consisted in the exhibition of the nitrate of silver commencing with the one-sixth of a grain three times daily gradually increased to one-half grain. This was interrupted every three weeks for a week, in order to avoid staining the skin. The electric brush, with a strong secondary Faradic current, was applied a few times down the spine, but the pain was so intense it had to be discontinued, and I substituted the revulsive action of the thermo-cautery, applied twice a week on the side of each vertebra, as the application was made very rapidly, the pain was very slight.

At the end of three weeks of this treatment, he was able to walk with the help of a stick; at the end of six weeks, he was able to go up and down stairs, and at the end of ten weeks, he went home almost well. I advised him to procure a McIntosh galvanic battery and use it daily, and also the nitrate of silver for two months longer.

He is now perfectly well and without a trace of disease.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——In a reprint before us discussing the operation of tracheotomy, Dr. Joseph E. Winters maintains that this surgical procedure, if properly performed, involves little danger to life and for many reasons should be resorted to much more frequently than is now the custom.

——A successful case of relief of a distended frontal sinus by interior local treatment is reported by Dr. C. J. Kipp, of Newark, N. J. In a paper from the Transactions of the American

Ophthalmological Society, he makes the important observation: "Attempts to empty the sinus through its obstructed or closed passage into the nose by digital pressure on the swelling should be made from time to time, and after the sinus has been once emptied it should be evacuated at short intervals. If, after a fair trial of this treatment, the distension continues, the old method of treatment may be resorted to."

——The address in medicine, by Dr. W. H. Daly, before the Pennsylvania State Medical Society, has been issued in neat pamphlet form.

——The National Temperance Society of New York, has republished Dr. B. W. Richardson's inaugural address, entitled "The Medical Profession and Alcohol." As is well known, Dr. Richardson is a teetotaler, and strongly urges the profession to join him and his party in what he calls "the supreme effort which is now being made, with every prospect and certainty of ultimate success, to rid the world of the slavery of superstition, folly, sin, sorrow, madness, and death that has for ages past been imposed upon the world by the use of alcoholic drinks."

BOOK NOTICES.

The Science and Art of Surgery. By John Eric Erichsen, F. R. S., LL. D., etc., eighth edition. Revised and edited by Marcus Beck, M. S., etc., vol. II, pp. 1205, Philadelphia, Lea Bros. & Co., 1885.

Not long ago we announced the appearance of the first volume of this highly esteemed work. The present issue completes it, and presents to the student a most valuable treatise, and to even the best-read surgeon a mine of information in which he will be sure to discover something which he will be glad to learn. In these compact volumes all the acquisitions of modern surgery are carefully recorded, and appraised with the skill of a master. Nearly a thousand illustrations enrich the pages, and add much to the interest of the text. An excellent index completes the second volume.

A Handbook of Pathological Anatomy and Histology, with an introductory section on post-mortem examinations and the methods of preserving and examining diseased tissues. By Francis Delafield, M. D., etc., and T. M. Prudden, M. D., etc., 1885. Cloth, 8vo., pp. 575. Wm. Wood & Co., New York, 1885.

This is the second edition of Dr. Delafield's work, but the scope of it has been so much extended that it may be considered as a new production. In its present form it contains minute instruction in the methods of making post-mortem examinations, of preserving diseased tissues, of preparing them for examination, and of cultivating and examining bacteria; also a description of the pathology of the processes of inflammation and degeneration of structure, the histology of the various forms of tumors, and of the lesions of the different parts of the body, of general diseases, of violent deaths, and finally of the appearances in cases of poisoning.

We need scarcely say that these topics are treated with great thoroughness, and the facts set forth in excellent language. The wide experience of the authors makes itself manifest on every page. The statements made are the result of personal observation, and are set forth with that clearness which direct study alone can give. The illustrations are numerous, and all of them are original, and drawn from actual specimens.

Our Bodies: Or How We Live. An Elementary Text-book of Physiology and Hygiene. By Albert F. Blaisdell, M. D. Pp. 285. Price sixty cents. Lee & Shepard, Boston.

The author of this school text-book describes with brevity and clearness the anatomy, physiology, and hygiene of the human frame; touches on dietetics and exercise; gives instructions for the care of the sick; teaches various practical experiments of a simple character, and adds references to a number of authorities for the benefit of those who might feel a desire to study the subject more at length. It is one of the best school treatises on this branch which has come to our notice.

Annual Report of the Supervising Surgeon-General of the Marine Hospital Service of the United States for 1884. Pp. 308. Washington, D. C.

The medical reader will find a great deal of instruction in this volume. It is by no means confined to the dry statistics of the service. Nearly a third of the pages are taken up with the descriptions of selected cases from the hospital practice of the surgeons of the corps, generally related with much minuteness and care. There are also special detailed reports on the yellow fever and a selection of reports from the United States Consuls on the cholera epidemics of last year, which it is quite possible may be appropriate reading for the coming summer. Other timely questions, as that of quarantine, the importation of rags, the hygiene of the merchant marine, the care of seamen on shore, and the like, are also discussed in an instructive manner.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address

DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

MAN AS A COOKING ANIMAL.

When Dr. T. Lauder Brunton says anything, he generally says something good. In the course of his lectures on "Disorders of Digestion," published in the English journals, he very truly says that "man has been defined as a cooking animal," and holds that while some of the lowest races are unacquainted with methods of cooking, yet on the whole the definition is true, for one of the most marked distinctions between man and the lower animals is that while the former cooks his food, the latter eat theirs raw.

That man is wise to be a "cooking animal," no one who hesitates to reflect will deny. That well-cooked food is much more easily digested than that which is indifferently prepared is a truism, though admitting of a relative definition and application. Of course, the laboring man can digest the coarsest kind of food, and derive from it nourishment for his muscles, that enable him to do physical work that, being directed by others and requiring on his part simply muscular effort, must be placed on a plane but little above the labor that is performed by the lower animals, who belong to the *non-cooking* class.

But let the man who combines mental and physical labor—he who constitutes the highest type of manhood—endeavor to nourish his muscles and his brain on similar food similarly prepared to that of the day-laborer, and we warrant you that in a very short time his digestion will suffer, and the results of his labors will be of an inferior nature.

We do not mean that he who wishes to work well should live upon the richest and most highly seasoned food, that he should be an epicure, as the word is commonly understood; though it seems to have been an epicurean dinner given by one of the City Companies of London that caused Dr. Brunton's enthusiasm on the subject of good cooking.

It may be that an English epicurean dinner is a much simpler and more substantial and less injurious affair than those to which we are accustomed in this country; if so, then we have no fault to find with it.

However, the fact remains, that good cooking is one of the most important and at the same time one of the most neglected aids to good digestion among the people of our country.

That what might be called "fancy" cooking is appreciated by many, is evidenced by the exorbitant wages commanded by the cooks of our best restaurants, hotels, and clubs, and the avidity with which all who are able, avail themselves of the products of these autocrats of the kitchen; but that *good* plain cooking is comparatively rare among the mass of our housekeeping population is an undoubted truism. We all know that pleasant impressions made upon our senses is the great secret of healthy life, the great lever that causes harmonious performance of all our vital functions; do we know not also that the impression of a well cooked dinner is a most potent aid to digestion, and do we stop to realize how grievously this aid to health is neglected.

Commenting on the advantages of a variety of articles of food, Dr. Brunton says:

"The common order of courses in a plain dinner is soup, fish, joint, pudding, bread and cheese, and dessert. The reason why soup comes first, has been admirably shown by Schiff in his experiments on digestion. This physiologist found that the stomach of an animal which some time before had digested a full meal, had very little power to digest albumen introduced directly into it; and a similar fact was ascertained in regard to an extract made from the stomach itself, this extract hardly acting on albumen at all. The stomach seemed to be exhausted by the effort of digesting a full meal several hours before, and to be incapable of producing pepsine. But if certain substances were introduced first into the stomach, the power to digest albumen was enormously increased. To these substances Schiff gave the name of 'peptogens,' and the most powerful of them he found to be dextrin, and soup made from meat.

"If the human stomach resembles the stomachs of animals in this point as it does in others, then we may say that usually the power of the stomach to digest such substances as hard-boiled eggs or boiled meat, when these are taken alone, will be very slight. But if the meal be begun with a plate of soup and a piece of bread, the bread partly converted into dextrin in the mouth, and the extractive matters of meat contained in the soup, on reaching the stomach, will be absorbed, and will supply to the gastric follicles the power to secrete an abundance of pepsine. In this country, where our butcher's meat is tender and juicy, we not unfrequently find that people in the middle of the day will take a beef-steak or a mutton-chop without soup. In this case, the savory soluble substances are quickly extracted from the meat in the stomach itself, and, being absorbed, supply the necessary secreting power to the gastric glands. But in other countries, where the animals slaughtered for food are often old and tough oxen, which have been employed for years in agricultural service, the meat, being less savory and juicy, will not yield peptogenic matters so readily to the stomach. Consequently, the Frenchman generally boils his butcher's meat thoroughly, and adds pieces of bread to the soup with which he begins his meal, so that the stomach can absorb sufficient peptogenic substance before the hard and tasteless boiled beef is swallowed.

Next to the soup, as I have said, usually comes fish, which is digested more easily than butcher-meat. I have already mentioned, more than once, that the rapidity with which anything dissolves depends very much on the fineness with which it is divided. Now, this is quite true of the different kinds of meat. Beef is acknowledged to be less digestible than mutton, and mutton less digestible than fish. The breast of a chicken is also reckoned very digestible. If we compare these different kinds of flesh, we will find that in beef the fibres are longer and harder than those of mutton, and those of mutton longer and harder than those of the breast of a fowl. The muscle-fibres in fish are arranged in flaky masses, and are not only very short, but are very readily separated from one another. We see, then, that the different digestibility of these different kinds of meat corresponds exactly with the readiness with which the muscle-fibres can be broken up mechanically. That it is the physical conformation of the muscle-fibres, rather than anything peculiar to the animal from which they are derived, is shown, I think, by the fact that, although the breast of fowls is universally acknowledged to be readily digestible, the legs, in which the muscular fibres are long and hard, are by no means specially adapted for weak digestions. With the meat, come vegetables, which are not only useful as supplying inorganic salts, but probably play a considerable part in aiding the recomposition of peptones into albuminous material of the tissues, after their absorption.

After the meal come the bread, cheese, and dessert. The bread will, no doubt, supply additional dextrin, and the cheese additional albuminoids; but, if we direct our attention only to the stomach, and to the chemical changes which are going on in it, it is not quite easy to see why bread, cheese, and dessert should be taken at the end of dinner. If we turn our attention, however, to the circulation and the nervous system, and remember the effect which I have already mentioned as produced upon them by the mastication and deglutition of savory food, we can at once see a good reason for the common manner of terminating a dinner. In order to supply abundant gastric juice for the digestion of the food introduced into it, the stomach requires an abundant supply of blood, and the nervous system must be kept active in order to respond to the calls made upon it. The savory cheese, swallowed in small morsels, and the sweet fruits, which strongly stimulate the nerves of taste, or nuts, which require considerable mastication, cause an abundant flow of blood to the nerve-centres; while the frequent movements of swallowing stimulate the heart, and increase the rapidity of the general circulation."

ABOUT GRAY HAIR.

The heroine of a popular play is made to exclaim that she never considers a man old until he is fat and bald.

She was quite right in omitting gray hair as a sign of age. Though it is generally esteemed so, there are too many exceptions on both sides to allow it as an infallible sign.

Many persons begin to show gray hairs while they are yet in their twenties, aad some while in their teens. This does not by any means argue a premature decay of the constitution. It is a purely local phenomenon, and may co-exist with unusual bodily vigor. The celebrated author and traveler George Borrow turned quite gray before he was thirty, but was an extraordinary swimmer and athlete at sixty-five.

Many feeble persons, and others who have suffered extremely both mentally and physically do not blanch a hair until past middle life; while others, without assignable cause, lose their capillary coloring matter rapidly when about forty years of age.

Race has a marked influence. The traveler, Dr. Orbigny, says that in the many years he spent in South America he never saw a bald Indian, and scarcely ever a gray-haired one. The negroes turn more slowly than the whites. Yet we know a negress of pure blood, about thirty-five years old, who is quite gray.

In this country, sex appears to make little difference. Men and women grow gray about the same period of life.

In men the hair and beard rarely change equally. The one is usually darker than the other for several years; but there seems no general rule as to which whitens first.

The spot where grayness begins differs with the individual. The philosopher, Schopenhauer, began to turn gray on the temples, and complacently framed a theory that this is an indication of vigorous mental activity.

The correlation of gray hair, as well as its causes, deserve more attentive study than they have received. Such a change is undoubtedly indicative of some deep-seated physiological process, but what this is we can only ascertain by a much wider series of observations than have yet been submitted to scientific analysis.

NOTES AND COMMENTS.

The Relations Between the Teeth and the Womb.

Dr. S. W. Caldwell, of Trenton, Tenn., publishes the following peculiar case in the *Mississippi Valley Medical Munthly*, January 10, 1885:

Recently, while spending the night in the sick-room, I had as company a married daughter of my patient, an intelligent lady, aged about thirty-two years, who related the following—to me—most singular phenomena. Said she: "I am the mother of five living children, one dead. My terms of gestation are unmarked by anything unusual. My labors last about eight hours on an average. My last came as usual with me—pain beginning in the back, passing down to the lower part of my bowels. When I had been in labor about an hour, the pain suddenly ceased in my back and womb, but set up in a tooth that had been aching several times during the past nine months. The pain was paroxysmal, coming and

going just as it did in the womb. The pain was in my tooth when my physician came, and he wanted to pull it, but it being one of but few remaining molars, I said to him that the cavity in it was small, and that I wanted to have it filled—couldn't he put something in it and stop the aching? He put cotton saturated with chloroform in the cavity. The pain left the tooth to appear in the back and womb; but the effect soon passed off; the pain in a few minutes returned to the tooth, to be again and again relieved by the chloroform; the doctor said no progress was being made in the labor, and that in his opinion none would be till that tooth was removed."

"Did he say he had ever seen or heard of such a case before?"

"No, sir. Twelve hours had now passed; my former labors had none gone over eight—generally six hours terminated them. I had become, I thought, exhausted, and asked the doctor to pull my tooth, which he did, and my baby was born in an hour."

The attending physician in the above case, and with whom I was personally well acquainted, died not long after, so that I cannot have his history of it. My knowledge of the lady, though, justifies me in giving full credence to her statement.

Tabes and Progressive Muscular Atrophy.

But few cases have thus far been reported, where locomotor ataxia was associated with progressive muscular atrophy. Eulenburg describes a case of this kind in the *Deutsche Med. Zeit.*, Dec. 22, 1885. In his case also the sclerosis of the posterior columns preceded the outbreak of the atrophy. After the patient had suffered for ten years from most symptoms of tabes as, sensation of a constricting band around the lower part of the chest, lancinating pains, gradually increasing uncertainty in walking and standing, severe gastralgic attacks recurring every 2–4 weeks with persevering vomiting and a peculiar left-sided headache, disturbances of the bladder, myosis and immobility of the pupils, and about six months ago the phenomena of progressive muscular atrophy made their appearance. First some muscles of the thumb of the right side, and then those of the left were attacked, afterwards the other muscles of the thumbs, and then those of the small fingers, the interossei and the extensors of the hands. Thus far the atrophy is limited to the muscles of the forearm; the muscles of the back evince but a peculiar weakness, and the atrophic arm-muscles show a decided diminution of electro-muscular contractility, some of them not at all responding to the faradic current, while the galvanic irritability is either diminished, increased or otherwise affected with the general formula of ACC>KCC (anode, closure, contraction stronger than anode CC, the opposite of the normal reaction).

From the post-mortem examinations of other cases, it is to be presumed that we have in these rare cases a complication of the posterior sclerosis with the characteristic lesions of neurotic progressive muscular atrophy, *i. e.*, with degeneration and atrophy of the large (motoric) ganglion cells of the anterior cornua, especially of the cervical spine. Charcot is of the opinion that the disease spreads to the anterior cornua by means of the inner fibres of the root-fibre-path as first indicated by Köllicker, for these fibres pass directly to the exterior group of cells. Eulenburg, however, believes that in some cases this connection cannot be proven, when the complication must be considered an accidental complication, probably originated by the same poison that gives rise so frequently, if not always, to locomotor ataxia of syphilis.

Diagnostic Errors and Practical Hints.

The following little article which Dr. A. B. Tadlock publishes in the *Nashville Journal of Medicine and Surgery* for February, 1885, is well worthy of note. He says:

"Other things being equal, we should say that a correct diagnostic rule would always lead to correct diagnostic conclusions; but the crucial tests of experience, even in this day of scientific perfection and wisdom, will occasionally teach us that *rules*, like facts and theories, may be incorrect, though recognized, practiced and taught for ages. In an interesting article by J. W. Long, M. D., he speaks of an arm presentation in a protracted case of labor in which he was consulting physician, as follows: 'Upon making a digital examination I found the little fellow's protruding hand fit my left hand, exactly as though we were shaking hands—thumb to thumb, and palm to palm.' Remembering the rule laid down in the books, the writer adds: 'The diagnosis flashed across my mind in an instant—the child was lying across the pelvis, its head to the right, its back to the front.' (Page 551, Dec. No.) Not many years ago a similar case, under very similar circumstances, occurred in my practice, and while 'the indications were plain enough,' as he says, still the mode of turning according to the rule was not as satisfactory, for the reason that the head was directly in the opposite flank from that

in which the 'shaking hands rule' required it to be. The child's hand was turned and lay behind its back. So the exception to the accepted *rule* was verified. This can be easily demonstrated by any one shaking hands with some person whose back is turned towards him.

"On page 537 (same No.) we find the history of an interesting exploit after a misplaced hairpin. In my first years of practice I found the same sort of a pin in a like predicament, and equally unsatisfactory to its locator, and puzzling to the prospective dislocator. Removal was effected, however, by passing a perforated gum catheter over one end of the pin when exposed, and then by pushing the catheter it was forced around the bend of the pin and back over the opposite end, and thus entirely encased, extraction was accomplished easily by the removal of the catheter."

Rectal Alimentation.

This subject is so interesting and important that we cheerfully reproduce the following case which Dr. Taylor reports in the *Cincinnati Lancet and Clinic*, February 7, 1885:

A married woman, twenty-five years of age, had had purpura hemorrhagica; she recovered from this sufficiently to take a trip, and seemed to be well when she came home. Suddenly, she was affected with a most excessive uterine hemorrhage, which came on at the time of her normal menstruation. The speaker was summoned and found the woman very pale and much prostrated, with great coldness of the surface and of the extremities particularly; a pulse of 140, weak and thready; and vomiting of the most aggravated character. The vomiting was constant, and everything swallowed was instantly rejected by the stomach. Three teaspoonfuls of ice-water were vomited as soon as taken. No nourishment whatever could be given to the patient in the ordinary way. The speaker, therefore, ordered an injection every three hours of four ounces of milk with ten drops of denarcotized opium; this was continued for ten days, and nothing else given, though attempts were several times made to administer nourishment by the mouth, but this was invariably followed by severe vomiting. However, the serious symptoms gradually disappeared; it finally became possible to give the patient food and medicine by the mouth; she became stronger, and had a better color. During the whole time the woman was very thirsty, and would beg for water, but this was instantly rejected.

The bowels moved once in a couple of days, the passages being soft; the urine was very little in amount. There was no hysterical element in the case, though the woman was nervous.

Should a Person Affected with Psoriasis Marry?

This interesting question was brought before the New York Dermatological Society (Dec. 23, 1884,) by Dr. Piffard, who said that he had a patient suffering from a moderate psoriasis, who asked him his opinion as to the propriety of marrying. Dr. Piffard said that he would like to have an expression of opinion from the members of the Society, on the subject.

Dr. Taylor said that he had seen many cases in which psoriatic patients had perfectly healthy children. In giving an opinion, he would be influenced by the length of time the eruption had existed, as well as its activity. If the question were propounded to him, he would say that if the patient suffered continuously from the disease, or if the attacks were severe, he would advise the patient not to get married; but if the attacks were ephemeral, he did not see any objection to marriage. In his mind there was no question as to the heredity of psoriasis, but it was generally in inveterate cases of long standing.

Dr. Sherwell could see no reason why a patient thus affected should not get married. He looked upon psoriatic patients as among the strongest persons. He had seen only one unhealthy patient, among several hundred, and he had fibroid phthisis. In fact, he believed that the occurrence of psoriasis was an indication of health.

Dr. Robinson would certainly advise psoriatic patients not to get married, unless there was some other good reason aside from the question of health. He said that psoriatic persons were often unhealthy, and cited a case of a patient with psoriasis in whose immediate family two persons died of phthisis and another had scrofuloderma.

The Effect of the Ingestion of Large Quantities of Grape Sugar on the Urine of Children.

Concerning this interesting physiological question, Dr. John M. Keating tells us in *The Therapeutic Gazette* (January 15, 1884,) that his attention has so frequently been called to the fact that sugar, to a greater or less amount, is found at times in the urine of persons who are supposed to be in excellent health, and the question has so often arisen whether or not diet has anything to do with this, that he determined to satisfy himself by a series of investigations as to the correct interpretation of this condition. He has had under observation at various times numbers of

infants whose diet was composed of milk and *Mellin's food*. Some of them took as much as an ounce and a half to two ounces of Mellin's food during the twenty-four hours. This consists, as is well known, of malted grain, a large part of the starch of which has been transformed into grape sugar. He has failed to detect a single trace of sugar in the urine of any case of this kind examined so far; and as all these children are in excellent health, he is led to conclude that the appearance of sugar in the urine of adults, whether it is or is not traceable to the diet of the individual, is an evidence of, at least, functional derangement which demands careful investigation. From these experiments he believes that if we can draw an analogy between a healthy infant and an adult—and he sees no reason why we should not—a sugar diet, unless in very great excess, in a healthy individual ought not to produce saccharine urine; if such is found, disorder or disease is probable.

Lepra and Tubercle-Bacilli.

One author after another is added to the list of those who are convinced that the tubercle-bacilli really are the pathogenic cause of tuberculosis. But the latest investigations have demonstrated the great difficulty which the observer has to overcome in the recognition of these bacteria. The lepra-bacilli are so very similar, not only in their appearance and in their reaction to coloring matter, but also in their behavior under pure-culture, that in cases of doubt the diagnosis becomes exceedingly hazardous.

We have to be grateful to Dr. V. Guttmann, who at the last meeting of the Berlin Medical Society communicated a method by which the distinction of the two species of schizomycetes becomes a much easier one. Guttmann says that they may be recognized without difficulty in dry preparations on the slide, but not by their appearance, but by their position. The tubercle-bacilli of the sputum are never seen in cells, but always perfectly free, and the same holds good of the tubercle bacilli from caverns, as they anyhow contain but the detritus of cells. But the dry preparations on the slide, of lepra-bacilli, though partly also free, are met with in immense numbers, mainly in cells, which on the slightest pressure may be easily discerned in the lepra-fluid.

With the usual method of coloring by anilin tints (red and blue), the lepra-bacteria are at once recognized, for they appear as red rods in blue cells, and the latter are so numerous as they never show themselves in case of tubercle-bacilli.

Sleeplessness.

A foreign exchange very truly says that sleeplessness is really wakefulness, and that before we resort to stupefying drugs to remedy this condition, we should inquire into the cause and remove it if possible. The cases of Napoleon and other busy men, who develop the power of self-induced sleep to such an extent as to be able to rest whenever and wherever they please, for longer or shorter intervals, as the conditions admitted, are quoted. We know that excessive mental work, worry, the abuse of alcoholic beverages or anything that will tend to keep too much blood in the brain, will ultimately produce a chronic engorgement of that organ that will render physiological sleep almost an impossibility. We have known insomnia, due to excessive alcoholic indulgence, to be very effectually relieved (and permanently so) by the application of dry cups to the nape of the neck. To discover the cause, will, of course, in many cases, take time, and involve a scientific testing of the relative excitabilities of the sense-organs, central or radial and peripheral. The discovery of the cause, however, affords ample recompense for the trouble of searching for it. With the sphygmograph and a few test appliances, such as Galton's whistle, an optometer, and other instruments, the recognition of the form and cause of sleeplessness can be made in a brief space, and then, and then *only* we protest, it can be scientifically—i. e., physiologically—treated.

Rheumatic Glossitis.

From a foreign exchange we learn that an alleged case of rheumatic glossitis is recorded by Dr. Carvallo in *La Cronica Médica*. The patient was a man aged forty, who one day found that his tongue began to enlarge and that articulation was difficult. The swelling increased so much that the tongue was no longer confined in the limits of the mouth. There was much difficulty in breathing; the lips were blue; the pulse was small; salivation was incessant; deglutition was painful; speech was impossible, and at times attacks of suffocation threatened dissolution. Leeches were applied to the angles of the lower jaw. Dr. Carvallo remembered to have read in M. Jaccoud's "Traité de Pathologie Interne," that Lawrence had written of the occurrence of glossitis as a consequence of rheumatism. The patient admitted that he had had rheumatism, and that he even then had rheumatic pains about the shoulders. An infusion of jaborandi was prescribed, and afterwards a draught containing sali-

cylate of soda. The next day the tongue had diminished greatly in size, and had returned to the buccal cavity. The suggestion that such cases of swelling of the tongue may depend on a rheumatic agency is perhaps valuable; the proof that the case mentioned was of rheumatic nature cannot be said to have been given.

Infants' Food.

This much-discussed question has been again discussed before the Obstetrical Society of Cincinnati (*Obstetric Gazette*, January, 1885), by Dr. J. L. Cleveland, who, in concluding his paper, remarked that while the members of the society might differ in the minutiæ of infant diet, in the main they were all agreed. The mother's milk contains all the ingredients necessary to the maintenance of the child, and so does the cow's milk.

There is too much caseine in the latter, which when coagulated forms a hard, indigestible mass. This may in a great measure be avoided by adding water, oatmeal, barley, etc.

One great difficulty in the management of the diet of infants is the lack of judgment on the part of the nurse. Every time the child cries it is supposed to want food, when often it cries because it has had too much food.

We can not be very positive in our recommendations of artificial food. What may answer well with one child may be found to totally disagree with another. He thought it very important to impress on the mind of the nurse the necessity of offering the child water at certain intervals. It helped to prevent the formation of hard masses of caseine, and the digestive juices acted better in its presence, when given in moderate quantities.

Cocaine in the Removal of Foreign Bodies from the Eye.

Still more about cocaine. In the *London Med. Times*, January 31, 1885, Dr. A. MacGreggor reports the following case:

A farm servant, while engaged working at a threshing machine, was struck on the right eye by part of a husk of corn with such force that it was firmly embedded in the substance of the cornea. He consulted me two months afterwards, and at that time, near the inner edge of the cornea, there was a large ulcer, the floor of which was covered with greyish lymph, but he could see no foreign body. The man, however, said he was certain the offending particle was still there. He applied a 10 per cent. solution of hydrochlorate of cocaine; in ten minutes the cornea was insensitive; he gently scraped the lymph away, and, much to the delight of the patient, removed a thin piece of husk more than an eighth of an inch long and a sixteenth broad.

Considering the length of time the foreign body was allowed to remain in the cornea, the signs of irritation were wonderfully slight, due, no doubt, to the atropine ordered by the gentleman who saw the patient soon after he received the injury.

Rheumatic Pains.

Constantin Paul recommends in the *Union Méd.* in cases of rheumatic pains as in lumbago, torticollis, pleurodynia, intercostal neuralgia, sciatica, etc., the covering of the painful parts with a compress saturated with oil of turpentine, but considers it important to place some impermeable substance, as gum cloth, oil silk or wax paper, over the compress, for in cases where such a protective had been omitted, the effect was not so favorable. It is probable that there is some virtue in these remedies, for crude kerosene oil, so nearly related to turpentine, has frequently been employed in this country for the same purpose, and not seldom stopped the pain. If no impermeable substance be laid over the compress, the rapid evaporation of the turpentine probably diminishes the effect of the drug, which can act only as a counter-irritant, and its irritating action must, therefore, be the greater, the more concentrated the remedy.

Extirpation of the Kidney.

At the December meeting of the Paris Academy of Medicine, Dr. Le Dentu presented a patient in whom he had extirpated three years ago the left kidney to remove a urinary fistula which, after an operation for a hydronephrosis, had remained unclosed in the iliac fossa. After the extirpation of the organ, the abnormal flow of urine at once ceased, but another fistula remained, which discharged pus. To establish its cure, Le Dentu left a drainage tube in the channel. When the discharge of pus had dwindled to a minimum, the tube was removed, and two days later the fistula closed.

The patient passes since the operation about three pints and two ounces of urine daily, and the urine itself is normal and free from morbid contents. It is not possible to demonstrate either by palpation or in any other way an enlargement of the remaining kidney.

The action of the heart is normal, and evinces not the least disturbance.

News and Miscellany.

Notes on Medico-Legal Cases.

BY HENRY A. RILEY, ESQ., NEW YORK.

In a Wisconsin court there was recently an interesting discussion in reference to the right of an insane criminal to a regular trial of the issue by a jury at the same time that the criminal charge was tried, and it was held that there was no such right. The person was under indictment and about to be tried when the district attorney informed the court that there was a probability that that the accused was insane and unable to care for herself, and the court thereupon ordered an investigation. A jury was impanneled to try the special issue, and having found the accused insane, the trial was indefinitely postponed, and the criminal committed to an insane asylum, there to be kept until a recovery would permit of the trial. An appeal was taken from this order, and the higher court, after a careful examination of the statute, declared that it was legal.

An interesting statement is given of the common law bearing on the subject, and it was stated that if a criminal became insane after the crime was committed and before he was arraigned, he was committed to prison until the disability was removed. The same course was taken if he became insane after the plea of not guilty was put in, and before the trial. If there was any doubt as to the insanity, the question was usually tried in a summary way by a jury.

In such cases it was, however, in the discretion of the court whether to try the preliminary question of insanity by a jury, or adopt some other mode. In one case the Attorney-General prayed an inquest, which was immediately granted, and the investigation was proceeding in a summary way, when Lord Denham, C. J., stopped the prosecution from calling any further witnesses, and virtually charged the jury to return a verdict of insanity, which they did. The prisoner was thereupon ordered into custody until the further direction of the Queen was made known. The court was authorized to make inquisition of the insanity of the prisoner by a jury or otherwise, as it deemed most proper. The inquisition was only preliminary to the trial of the offence, and had no bearing on the guilt or innocence of the prisoner. It was entirely collateral to the main trial, which was indefinitely postponed until the prisoner's sanity and capacity to act for herself on such a trial should be restored. The statute certainly did not give a jury trial as a matter of right upon such collateral issue. Undoubtedly it may, in a proper case, make such inquisition by a medical commission or otherwise, at its discretion.

In the time of Sir Matthew Hale it was said there were "two sorts of trials of idiocy, madness, or lunacy; the first, in order to the commitment or custody of the person and his estate, which belongs to the king, either to his own use and benefit, as in case of idiocy, or to the use of the party in the case of accidental madness or lunacy; and in order hereunto there issues a writ or inquisition to the sheriff or escheator or particular commissioners, both by their own inspection and by inquisition to inquire and return their inquisition into chancery; and thereupon a grant or commitment of the party and his estates ensues; and in case the party or his friends find themselves injured by the finding him a lunatic or idiot, a special writ may issue to bring the party before the chancellor or the king to be inspected." The course outlined in the Wisconsin case is a very common sense one, and has been adopted by a number of the States, and noticeably so by New York, where the abuses of trying the issues of insanity and guilt at the same time were glaringly manifest.

—

A curious case on insanity is reported in a Missouri court, where the question arose as to the validity of a tax title to real estate, the owner having allowed it to be sacrificed because of a delusion that Christ had forbidden the payment of tribute, except to the church. In consequence of this idea he refused to pay any taxes, and the land was, after a time, sold. Subsequently a suit was brought to set aside this tax deed; and as it appeared that the insane person had not been represented on the trial by a guardian, and the purchaser was aware of the insanity, the relief asked for was granted.

—

The Dairy Commissioner of New York has just made his annual report to the Legislature in regard to the working of the law passed at the last session absolutely prohibiting the manufacture and sale of oleomargarine. He states that probably 80 per cent. of the traffic has been broken up by his efforts, and that sixty arrests have been made. Of this number, eleven have been convicted and forty are still under indictment. A test case has been made as to the constitutionality of the law, and is now pending. It is curious to notice that the opinion given by William M. Evarts that the law was unconstitutional was used as an argument by those opposed to his election as United States Senator from New York. The Legislature did not, however, pay much attention to the objection.

—

The powers of Health Boards are indirectly concerned in a suit just brought by a firm of cream-of-tartar mannfacturers at Edgewater, Staten Island, although the main point is that the Health Board of the town was illegally created, and had no real power at all.

The manufactory was thought to be a nuisance, so that the townspeople were greatly exercised over it, and as a result, a Health Board was at once appointed, and took active measures to suppress it. There were numerous threats to burn down the establishment, and so serious did the situation become that the proprietors became frightened, and closed up the works voluntarily. Having lost a good deal of money by this course, and believing that the Health Board was illegally appointed, the firm has brought suit against the town and its improvised Board, claiming $104,000 damages. The trial has not come off yet, but promises to be interesting.

—

A case was tried not long since in the United States Court at New York, to see if a person could

be held liable for taking his children, who were sick with the whooping-cough, to a boarding house, where there were a large number of people. The result was that the children of the landlady became sick, and the boarders in order to avoid the contagion left in a number of instances. The court held that a person had no right to spread the disease by taking his family about from place to place, and if he did so he was liable in damages. It was stated that taking infected animals from one place to another was negligence, entitling a person to sue for damages, and that there was even greater reason for holding the offender liable in the case of human beings. A motion for a new trial was therefore denied.

Sanitary Influence of Forest Growth and Public Squares.

Dr. J. M. Anders, of this city, read a paper on "Sanitary Influence of Forest Growth and Public Squares," before the Philadelphia Social Science Association, at the Hall of Mercantile Library, January 29, 1885. He began by stating that the remonstrances of the public press, as well as of scientific writers, against the wanton devastation of our primitive forests were not needless, and he cited the experiences of many European and Oriental countries in proof. Wherever, in past time, the forests have been cleared away by a people, the effect has been the drying-up of the smaller streams, followed by infertility of the soil, insalubrity of climate and frequently utter desolation. Forests have a mechanical influence. Clumps and belts of trees act as efficient interceptors of wind-currents, and modify extremes of temperature. They also afford efficient protection from malarial diseases. Forests are great natural dispensers of moisture, and exert considerable influence upon the hydrometeorology of the region in which any fair proportion of woodland exists. Forests produce ozone, and it cannot be questioned but that ozone is the chief natural purifying agent of the atmosphere from all organic matter. The influence of forests upon the soil and running streams cannot be over-estimated.

From these various influences of forest growth, continued Dr. Anders, it is quite clear that they exert a potent effect upon the salubrity and healthfulness of a locality. The proper ratio of woodland for ordinary hygienic purposes is not less than twenty-five per cent. Forests are capable of rendering valuable and energetic service in connection with health stations. Thus at a resort of medium altitude not more than fifty per cent. of forest area would produce an effect suited to cases of consumption requiring a comparatively dry climate. Again, in those predisposed by inheritance to consumption, a residence in an atmosphere such as that described would prove a most powerful prophylactic measure. In all the various conditions of consumption in whose treatment the element of dryness is indicated, the air of the pine grove offers advantages superior to those of forests composed of different species, for the reason that pine trees exhale less moisture, while they possess all the other advantages mentioned, such as the generation of ozone, protection from malaria, and objectionable wind currents.

The lecturer then passed to a consideration of the public squares, which, he said, might be looked upon as forests of reduced size, and nowhere could trees and ornamental shrubbery prove their virtues to greater advantage to public health than by improving the conditions of a vitiated city atmosphere. The same ratio of woodland for sanitary purposes (twenty-five per cent.) should be assigned for retreats of this kind, but as this would be impossible in those portions of older cities already densely built up, a near approach to the proper standard might be attained by the more general planting of trees on either side of our thoroughfares. This latter suggestion, if carried out, would have the effect of improving the air of the streets, which is really the air we breathe, and thus by means of free ventilation, a purer and wholesomer atmosphere could be admitted into our dwellings. Again, public squares form a convenient substitute for a more complete change of air in the cases of that large class of little patients suffering from infantile diseases of summer. There is no fact better established than that the usual summer ailments of infants can be most successfully treated by a change of air.

In conclusion, Dr. Anders said that there was no more important subject inviting the attention of municipal law-makers than that of open squares and their keeping up under proper regulations. He thought it no exaggeration to say that any improvements they might make in this regard would be rewarded by a realizing sense of having done the greatest good to the greatest number.

Good Advice to Physicians.

The following wise counsel we note from the *Maryland Med. Jour.*, January 17, 1885:

At this season of the year the practitioner of medicine is usually interested in gathering in the results of his past year's labor. It is eminently a time when his thoughts turn from the pursuit of scientific speculations to the every-day affairs of life, which must press with more or less weight upon all who struggle for the necessities of life. Whatever motives may actuate a few scientific devotees, the fact remains that the vast majority of medical men are working and toiling for bread and meat for themselves and for their families. The doctor has necessities, just as other people, and he generally works harder than the majority of people to meet these necessities. He has obligations to meet just as other people, and, as a rule, must depend upon his medical work to meet them. If, in addition to his scientific attainments, he possesses a fair allowance of business thrift and enterprise, his obligations are generally met, and the hand of penury presses lightly upon him. Unfortunately, however, a large number of medical practitioners are deficient in those qualities which go so far to make their toils light and their obligations easy. Many physicians are careless in money matters. They are poor collectors, and from this fact are often indifferent creditors. They are frequently too easy in demanding what is due them, and correspondingly careless in meeting their own obligations. In this way they lose a large share of their hard-earned services, and become, in consequence, involved in their responsibilities to

others. We have known a physician to mortgage his inheritance, to borrow money from banks and money-lenders, to meet pressing family expenses, rather than enforce collections from patients amply able to discharge their obligations to him. It is easy enough to see the result of such a method as this. A look into the homes and surroundings of the widows and orphans of many deceased medical men is a sufficient commentary upon this system of medical practice. The statement is often made that the profession is overcrowded, and is in great danger of impoverishment from this circumstance. We believe that the true danger is from another direction. It comes rather from the use of faulty methods of conducting practice, from neglect and carelessness in collecting bills for services rendered, from undercutting and underbidding for patronage. The effect of a system of lowering fees, and of careless collections, will affect an entire medical community. One physician can disorganize a whole section of a city, town, or country in which he may happen to reside, by adopting methods after this manner. Because a physician is engaged in a peculiar character of public service, is in itself no reason why his business methods should vary widely from those adopted by others who work for the public good. We certainly would not undertake to encourage a purely monetary view of medical work. The physician who sees only in his work a result in dollars and cents, has not the highest conception of his art.

But the physician should not confound his dual relations to the public. He should not be carried away by a false sentiment on the one hand, or a purely mercenary spirit on the other. There is just blending of the two, and he should aim to conduct his medical work on a basis that will insure respect, authority, and a just compensation for his services as a public servant.

To insure this respect as a doctor (teacher) it is just as necessary that he should be a man of integrity, of scrupulous honesty, and of correct business dealings as that he should possess medical attainments. The public does not always form its estimate of a physician by his skill or knowledge. Indeed, his moral and personal qualities may far over-balance his astuteness and learning. The man who seeks public patronage upon his scientific attainments and nothing else, is far less likely to succeed in securing it than the man who relies upon his moral and personal qualities with only a modicum of medical ability. In other words, the practitioner of medicine must be possessed of not only skill and learning, but of high moral, social, and personal qualities as well, if he would attain the highest position of respect and influence in any community.

Turning, now, to the purport of our remarks, the season of the year suggests a collection and settlement of accounts; it calls for a few weeks to be given up to business considerations. Let every physician make off his accounts, enforce their collection, and then discharge his business obligations. The surplus should find its way into safe and judicious investments. The inquiry may suggest itself, why venture such advice? We answer, we believe it is needed. Our work as journalists brings us into relations with many physicians. We know how careless and reckless many of them are in money matters. We know that many of them fail to collect what is due them, and many more fail to pay what they owe others. We do not attribute such failures to dishonest principles. On the contrary, we believe that many of these very men would give away their last cent if asked for it. They are generous, but not just. Their faults are the outgrowth of a recklessness and carelessness in matters of business, which, if applied to their habits as practitioners of medicine, would make them dangerous citizens to any community. Therefore, we say to those who are careless, collect what is due you, square up accounts, and lay aside a surplus for future use.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the week ended February 14, 1885.

Guiteras, John, passed assistant surgeon. When relieved at Key West, Fla., to proceed to Charleston, S. C., and assume charge Feb. 11, 1885.

Kalloch, P. C., assistant surgeon. To report to passed assistant surgeon Peckham, at Wilmington, N. C., for examination for promotion, Feb. 10, 1885.

Glennan, A. H., assistant surgeon. Relieved from duty at New Orleans, La., to proceed to Key West, Fla., and assume charge, Feb. 11, 1885.

RESIGNATION.

Heath, W. H., passed assistant surgeon. Resignation accepted by the Secretary of the Treasury, as tendered, Feb. 14, 1885.

Items.

—To keep the bowels open in dyspepsia Prof. DaCosta says the best thing is aloin gr. $\frac{1}{10}$–$\frac{1}{5}$ twice a day.

—Sir William Jenner, of London, commenced life as an apothecary in a small back street, and for a long time the battle of life fell severely on him.

—Prof. Bartholow speaks very favorably of the latest substitute for quinine, to wit: antipyrine; and says "it is a certain and powerful antipyretic."

—Dr. Piffard recommends a solution of the bromide of arsenic, one per cent., for pimples. One or two minims should be given in water before meals.

—In the *New Orleans Med. and Surg. Jour.*, Jan'y, 1885, Dr. J. McF. Gaston, reports a case of perforated fracture of the cranium, followed by epilepsy.

—In the *St. Louis Courier of Medicine* for Jan'y, 1885, Dr. Wm. C. Glasgow reports a case of aneurism of the aorta, communicating with the superior vena cava.

—A radically disposed aspirant for obstetrico-chirurgical fame, was once asked what he would do in a case of post-partum hemorrhage. He promptly replied, "dilate the os and search for bleeding vessels."

—Before a recent meeting of the Clinical Society of Maryland, Dr. C. W. Mitchell exhibited a spleen which weighed only one drachm. He

could give no history of the case; the individual was a large, well-nourished man.

—De Lavra (*El Siglo Medico*) gave extract of gelseminum in a case of refractory sciatica in a woman eight months pregnant. He gave three doses of one grain each. The cure was rapid and permanent.

—The Fellows of the Royal College of Surgeons of Ireland, have voted to concur with the Council of the College in having the charter altered, so as to admit women to all diplomas of the college on terms equal with men.

—The Cleveland, Ohio, Board of Education has issued an English version of the Brussels Manual for teachers, and adopted it for use in the public schools. This manual contains brief instructions as to the first symptoms of transmissible diseases.

—Labbe states that he has had favorable results with salicylate of soda in cases of sciatic and supra-orbital neuralgia, where quinine had failed. L. prescribes ʒij of salycilate of soda in the first two days; ʒj on the third day, before eating, with a little Vichy.

—Dr. F. A. Burrall, of New York, in the *New York Medical Record*, says that salt and water will readily cleanse the cups of the Gaiffé battery after they have been used. He adds, "those who use this convenient faradizer will, I think, appreciate the benefit of this information."

—A proposition was set on foot some time since to hold an International Conference on Sanitation. It is stated that the project, which was mainly initiated by Signor Manzoni, the Italian Minister for Foreign Affairs, will shortly take definite shape at a meeting to be held in Rome.

—In the *Archives of Medicine* for December, 1884, Dr. Henry B. Sands publishes a valuable paper on the rupture of veins, with the report of a case in which the rupture of a deep femoral vein was successfully treated by ligation of the ruptured vessel.

—Mayor O'Brien, of Boston, has appointed Drs. H. I. Bowditch, H. J. Bigelow, Francis Minot, R. M. Hodges, S. A. Green, J. G. Blake, W. L. Richardson, George B. Shattuck, and C. F. Folsom, an advisory committee in regard to the question of a possible epidemic of cholera next summer.

—Something very like heredity in crime was illustrated in a case which came before one of the Glasgow police-courts a few days ago. A boy of twelve years of age was found guilty of stealing a pot of marmalade from a cart in the street, and was sentenced to four years' detention on board a training-ship. In the course of the evidence it came out that at present the boy's mother, grandmother and uncle are in prison, while his father has deserted him.

OBITUARY NOTICES.

DR. LOUIS ELSBERG.

The death of Dr. Louis Elsberg, one of the best known laryngologists in this country, occurred February 19, 1885, in New York city. He was born in Iserlohn, Westphalen, forty-eight years ago, and came to America with his parents when only thirteen years old. His family settled in Philadelphia, where he graduated at the Jefferson Medical College in 1857.

Until recently, he was President of the American Laryngological Society. As one of the founders and a professor of the Polyclinic Institute, he accomplished much in elevating the standard of professional skill in the special branch of medical science to which his life was devoted.

Dr. Elsberg was connected with all the more important medical associations of this country, and sustained honorary relations with many similar societies abroad. His writings were extensive and his decisions universally accepted as authoritative. He was the editor of the *Archives of Laryngology*, and a regular contributor to Schmidt's *Jahrbuecher*. As the author of a work on the "Throat and Voice," he attracted much attention. He was a frequent contributor to the Medical and Surgical Reporter, and at one time took charge of a department in the *Compendium of Medical Science*. His death was attributed to pleuro-pneumonia.

WILLIAM BRAITHWAITE, M. D.

Mail advices from England announce the death of the well-known English physician and surgeon, William Braithwaite, the founder of *The Retrospect of Medicine*, who died at his home in Leeds on January 31. *The Yorkshire Post* of February 2, contains the following:

He was the oldest medical practitioner in Leeds, and in his large and varied practice he was esteemed on all hands, both on account of his great knowledge and his sympathetic and kindly disposition. Dr. Braithwaite was born in 1807, and was therefore in his seventy-eighth year. His health for some time past has been such as to cause serious apprehension on the part of his family and friends, and his death on Saturday was not altogether unexpected. He was brought up by the Rev. Richard Hale, at Harewood Vicarage, and was apprenticed to the eminent surgeon, Mr. Thomas Teale, and afterward to his equally eminent son, Mr. Thomas Pridgin Teale, so that he pursued his medical curriculum under exceptionally favorable circumstances. He also studied at St. George's Hospital. The deceased gentleman began practice in Leeds on his own account in 1830, and filled the post of honorary surgeon to the Eye and Ear Infirmary, and lectured at the Leeds Medical School on the diseases of women. Though occupied in the management of a large practice, he found time to add materially to the literature of his profession. In 1840 he began a medical work which has since become widely known. Its title is *The Retrospect of Medicine*. It is published half-yearly, and has now reached its ninetieth volume. It is republished in America, where it is widely known and as highly valued as here.

MARRIAGE.

CONE—DUNNUM.—January 31, 1881, in Brattleboro, by F. E. Tower, Dr. C. B. Cone and Nellie M. Dunnum, both of Springfield, Mass.

DEATH.

BIRD.—October 15, 1884, of typhoid fever, at his home, The Lindens, South River, Anne Arundel county, Md., William P. Bird, M. D., aged 58 years.

CLINICAL LECTURE ON DISEASES OF WOMEN, DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROF. T. GAILLARD THOMAS, M. D.

Reported for the Medical and Surgical Reporter.

EXTIRPATION OF THE UTERUS.

Gentlemen: Those of you who were present at my last clinic at the Woman's Hospital, six days ago, will be interested, I think, in hearing how the case in which I removed the entire uterus has been progressing since the operation; and it affords me great pleasure to tell you that there has never been any increase of temperature, or the slightest unfavorable symptom of any kind. The patient now, therefore, may be safely said to be out of danger, and already she has been removed from the isolated cottage in which the operation was performed, to a room in the general hospital building. This, I may say in passing, is the fifteenth case in which I have operated for the removal of the uterus; and of these fifteen, eight have recovered, while seven have proved fatal. In considering this percentage of deaths, however, it is well to remember that every one of these fifteen patients would certainly have died if the operation had not been undertaken. I am perfectly sure, also (or at least as sure as one can be of anything which he cannot positively demonstrate), that out of the next fifteen cases in which I perform this operation I can save a larger percentage of patients than this; for in looking back over those which have terminated fatally I can detect mistakes or lack of certain precautions on my part, which, without doubt, contributed to the unfortunate result.

OVARIAN TUMOR IN A YOUNG GIRL.

Our first patient to-day is Margaret H——, born in Nova Scotia, aged eighteen, and single. The history which she gives of herself is a very striking one in many respects. She says she has been sick for two years, and that up to two years ago she was perfectly healthy. At that time she had a very hard fall, striking flat on the abdomen, and the next day there came on a very severe uterine hemorrhage. This flowing continued for several months—three at the least—and she says she then called in a physician, who gave her some medicine, which gradually stopped it. Since then, however, there has never been any return of the menses; but as time went on, she noticed that her abdomen was gradually growing larger. She is now as large as a woman ordinarily is at the eighth month of utero-gestation, and she says there has been no menstrual discharge for at least eleven months.

The abdomen of this young girl presents, then, a large hard mass, and she comes here to-day to find out what the trouble is. Suppose that, instead of coming to the college, she had gone to the private office of any one of you. You can see at once that very delicate questions would have arisen for you to decide, and that a great deal would have depended on the diagnosis which you made; for the case is one of importance in many ways. In the first place, she might have slipped on a sidewalk of a city like this, and, attributing all her trouble to the fall, might have called upon you for an opinion which would justify her in

bringing suit for damages against the municipal authorities for the condition of the streets. Thus, next week I shall have to make an examination in the case of a woman who slipped and fell three years ago, and who ever since has suffered so greatly from dyspareunia, that marital life is a serious burden to her. In consequence of this she is bringing suit for $12,000 against the city, and I shall have to be extremely careful in expressing an opinion as to whether or not the trouble of which she complains is really attributable to the injury incurred in the fall.

Another important point to decide here is, what sort of an abdominal tumor is this, and what connection has the amenorrhœa with it? Perhaps the amenorrhœa may be natural, and the tumor a living one. As to the statement of the patient that it has continued for eleven months, that should have no weight whatever in affecting our opinion of the case. Many instances have, unfortunately, occurred in which the abdomen has been opened and the trocar plunged into a tumor supposed to be ovarian, which proved, to the operator's chagrin, to be nothing more or less than a gravid uterus. If utero-gestation should really exist, and you should express the opinion that this was not the case, or if just the opposite of this should be true, you can readily see in what an unpleasant position you might place yourself. Let me show you, then, how I would advise you to conduct your investigation in a case like this, in such a way as to avoid error and arrive at the truth. The problem you have to solve is, what is the character of this tumor, and what its connection with the uterine hemorrhage and the subsequent amenorrhœa?

What, now, might it be? It might possibly be any one of thirty or forty different things; but the most of these conditions are so exceedingly rare as to render it unnecessary to take them into account at all. What, then, are the things that it is really likely to be? First of all, in every such case you should always, without any exception whatever, think of utero-gestation. Even if it were one of the vestal virgins themselves, let this be the first supposition on which you proceed with your examination.

At the period of pregnancy, when the abdomen is as large as in the present instance, the cervix ought to be quite soft and a little patulous, and the markedly protuberant anterior wall of the uterus bulging in front of it; while through the os something hard (whether the head or the back of the child) should be felt moving up and down. Instead of this state of affairs, I found on examination here the cervix and uterus of a virgin, and venturing, on account of this, to pass the probe, it entered the cavity, which I ascertained to be empty for two and a half inches, and in a direction which showed the uterus to be turned backwards. But, notwithstanding all this, the patient might still be pregnant; for this might possibly be one of those rare cases where there is a double uterus. I began, therefore, my examinations on the outside of the abdomen. If in a case of pregnancy you keep your hands steadily upon the uterine tumor for some time, you cannot fail to detect a hard mass and the movements of the child. Then, with careful auscultation you ought to be able to distinguish the fœtal heart-sounds, and the so-called placental *bruit*. The latter is in reality a uterine *bruit*, however, as the sound is caused by the rushing of the blood through the uterine sinuses. Nothing of the kind was found in this case; nor were there any mammary indications, or any other sign of utero-gestation whatever. This hypothesis is, therefore, to be discarded.

Secondly, the abdominal enlargement might be caused by a large uterine fibroid; but in that case the tumor would be very hard and unyielding. Here, on the contrary, I can get a distinct wave on palpation. Has the patient, then, ascites, which might perhaps too be due to disease of the liver or of the peritoneum? If this were the case, there would be perfect resonance on percussion at the upper part of the tumor, from the fact that the intestines would float on the top of the water. There is, however, not a trace of resonance at the top, the percussion-note being perfectly flat at that point, while there is resonance at the sides, much more marked on one than on the other. She has not, therefore, ascites.

We arrive at the conclusion, then, that she is probably suffering from some form of cyst. This might possibly be of the liver, the kidney, or some other organ; but there is one kind of cyst that is so vastly more common than any other that we will be hardly likely to err if we conclude it to be of this character, and that is the ovarian. There are special reasons also for supposing it to be an ovarian tumor. The mass extends fully down to the pelvis, and it has pushed the uterus backward and downward, as we have previously ascertained. To show you how valuable I regard the former of these signs, I will mention that in a case in which I operated about six months ago, as soon as I found that there were intestines between the tumor and the iliac fossa, I confidently

asserted that whatever else the growth might be, it was certainly not an ovarian cyst. The result proved it to be an enormous cyst of the kidney, its size being one and a half times as large as my head.

So much for the diagnosis of the tumor: now for the question of its etiology. Let me caution you in the first place to beware how you give your support to the hypothesis (on which a suit for damages may be based) that because a certain difficulty from which a patient is suffering came after a fall or other injury, that it is the result of that injury. Some time ago a lady consulted me who said that she had a severe fall upon the back, and that profuse uterine hemorrhage had immediately followed. From her account, I supposed that it was probably a typical case of acute retroversion of the uterus; but when I made a vaginal examination, what was my surprise to find that instead of this there was advanced carcinoma of that organ. Yet the patient until that time had never had any hemorrhage or other symptom to indicate the presence of malignant disease. You must be on your guard, therefore, in regard to *post hoc, propter hoc*. I doubt not that the fall was the exciting cause of the hemorrhage here, but do not believe that either the hemorrhage or the amenorrhœa would have resulted if the ovaries had been in a healthy condition at the time of the accident. I am speaking only from experience; but in the light of that I do not hesitate to say that this girl's trouble is not due to any such cause. On the contrary, I believe that at the time she fell she had cystic degeneration of both ovaries. The fall, however, probably did cause the rupture of one or more of the ovarian cysts, and thus gave rise to the hemorrhage; while as the hemorrhage continued, the ovary went on increasing in size.

Finally, as to the prognosis. Unless ovariotomy is performed, it is a completely hopeless one. I need not say how fully established is the point that drugs are utterly useless in this affection. You will doubtless hear of many cases of ovarian tumors which have been cured without resort to the knife; but the explanation of this is, that they have not been true ovarian cysts. It not unfrequently happens that a patient comes to an ovariotomist with a tumor of considerable size, but because he thinks it is not at the time sufficiently large to demand removal, he tells her to return to him in six months; yet when she comes back to him at the end of that time, the growth may have entirely disappeared. This is because it was a par-ovarian cyst, a simple cyst of the broad ligament, which contained nothing but pure serum; and it is the cases of this character in which recovery takes place spontaneously, though the cure is generally attributed to whatever medicine the patient happens to be dosing herself with at the time.

This being, without doubt, however, a true cyst of the ovary, ovariotomy becomes imperatively necessary. When, then, shall the operation be performed? At once, I should say. The late Professor Peaslee, one of our highest authorities on the subject, was in favor of postponing the operation to the last possible moment, on the ground that the patient ought to be permitted to enjoy life as long as she could. But the fact is, that the patient cannot enjoy life with such a tumor. Its presence makes her utterly miserable, and after it has attained a certain size, the sooner its removal is accomplished the better; not only because of the inconvenience and suffering which she will be spared, but because her chances of recovery will be much better than if it is postponed too long. The tumor in the present case now, no doubt, weighs twenty-five or thirty pounds, and it is high time that it should be gotten rid of.

I feel almost certain that double ovariotomy will have to be performed here; and for the reason that the patient has not menstruated for eleven months. The fall, certainly, had nothing whatever to do with this, for women are continually meeting with all sorts of accidents and injuries, but they go on menstruating just the same if the ovaries are healthy. It is the cystic degeneration of these organs, and not the fall, which has put a stop to this young woman's menstruating.

CYSTS OF THE UTERO-VAGINAL GLANDS.

Mrs. Ann R——, thirty years old, has been married three years, and has had one child. This is a very acute case compared with most of those that we meet here, as she says she has been sick only eight days. Eight days ago she began to suffer intense pain, accompanied with a burning sensation, whenever she attempted to pass urine, and yesterday she noticed, for the first time, a lump gathering within the vulva. This is the history.

One of the great advantages of a clinic like this is, I think, that many of the cases which you see here are likely to present themselves to your minds when in the future you meet with similar ones in your own practice; and it may be that many years from now the memory of some special case here at the clinic may enable you to

successfully treat one of the same character which you then meet with for the first time yourself, and which might otherwise have proved a puzzling one to you. Thus, the present case may fix itself in the memory of some of you, just as one that I will now mention did in my own. Twenty years ago, a lady from the South consulted me for aggravated dysmenorrhœa; the pain coming on during the first day of the flow and being excruciating. It was before the days of the hypodermic syringe, and her suffering was so agonizing that nothing seemed to give her much relief. After remaining in New York for a number of months without receiving any permanent benefit, she returned to her home in the South, where some time afterward her physician removed a small fibrous polypus, hanging by a pedicle from the uterine canal; and after that she had no further trouble. The explanation of the case was, that this little fibroid, being comparatively free in the cavity, had acted like a ball-valve in preventing the escape of the menstrual blood, and thus set up the uterine contractions which caused the patient such extreme pain. Gradually, the fibroid worked itself downward along the uterine canal, until it was finally extruded from the cervix, when its removal became a very trifling matter.

Since then, I have never met with a case in which the symptoms were quite the same as in this case until this very day, when a lady came to my office who suffers in precisely the same manner. Whether the trouble is due to the same cause, I do not know; but with the experience of the other case in mind, I shall at all events take the precaution of dilating the cervical canal with sea-tangle, and examining to see whether there is not such a fibrous polypus present; and it probably would not have occurred to me to do this if I had not come across the other case twenty years ago.

In the case now before you, which, perhaps, may recur to some of you many years from now, there is a cyst of considerable size under the right *labium majus*, which is excessively painful to the touch; and under the left arm there is a similar, though smaller, cyst.

So much irritation have these cysts caused, that there is now quite a severe vulvitis in consequence. If you did not make a correct diagnosis, this case might give you a good deal of perplexity; but if you recognize its true character, you would find it one of the most curable cases to be met with in practice. These cysts are due to a degeneration of the vulvo-vaginal glands, whose excretory ducts have been closed by inflammatory action. The vulvo-vaginal glands were first described by Bartholinus, after whom they are often called; but, strangely enough, his description was entirely lost sight of for a long time, and they were rediscovered, as it were, by M. Huguier, of Paris, in 1841. When they become inflamed vulvitis, urethritis, and more or less vaginitis, are the results, as in this case, and coitus becomes utterly intolerable. In this condition all sorts of lotions and soothing applications are often ordered; but such treatment is absurd, for the reason that the ducts of the glands, as has been mentioned, are closed by the inflammatory action. If we could probe them with the same skill that the oculist does the lachrymal duct, good results might perhaps be secured by the operation; but I have never heard of such a thing being done. The treatment that I unhesitatingly recommend in such cases is to snip off a section of the cyst (having first anæsthetized the patient), and then stuff it with carbolized cotton. This cures permanently, because the gland soon disappears entirely after the operation. The French writers advise dissecting out the gland; but the great objection to this procedure is that a branch of the pudic artery is very liable to be severed in it, and as the artery lies very deep under the ramus of the pubes, it is difficult to control the hemorrhage that results.

COMMUNICATIONS.

SUCCESSFUL TREATMENT OF PSOAS ABSCESS.

BY J. M'F. GASTON, M. D.,
Of Atlanta, Ga.

A full report of this case is presented under the impression that these details are essential to a proper comprehension of its exceptional termination.

On September 29, 1884, the case of A. B. came under my care, he being a young man of vigorous constitution eighteen years old, who had been a student in a literary institute of upper Georgia, and had spent his summer vacation in the lower part of this State and in Florida. Some weeks previously he had pain in the lumbar region, with fever, for which sulphate of quinine had been taken, and a blister had been applied upon the right hypochondriac region.

When he came into my charge, there was a coated tongue and some sensitiveness over the kidneys, with a frequent inclination to urinate,

and he had torpid bowels. Upon testing the urine there were no evidences of albumen, nor was there any deposition of solid matter on standing. His disease had been mistaken for rheumatism by another medical attendant. With a view to correct the biliary function, and to relieve the renal irritation, he was prescribed:

℞. Calomel, 18 grs.
Nitrate of potash, 60 grs.
Mix and divide into 6 powders, of which take 1 every two hours.

Also he was ordered externally:

℞. Pomade of belladonna, 1℥.
Camphor, 1℥.
Iodine, 5 grs.
Iodide of potash, 30 grs.
Mix, and apply little by little over the kidneys and liver, with a poultice of flaxseed applied frequently to the same regions.

The medicine having operated, on the following night, September 30, he was directed as follows:

℞. Dover's powder, 12 grs.

Take with interval of 2 hours before bedtime. Chicken soup with rice was recommended as diet, with a cup of tea and toast night and morning.

October 1, 1884. The tongue remained coated to some extent, and the renal irritation had not disappeared, so that I prescribed the following:

℞. Infusion of buchu leaves, 10 ounces.
Syrup of squills, 2 ounces.
Soluble cream of tartar, 1 ounce.
Mix and take half a wine-glass every two hours.

Finding upon examination over the liver and kidney of the right side, a saliency with indications of local inflammation in their respective localities, four leeches were applied over each protuberance, with directions to apply subsequently cataplasms of flaxseed.

October 2, 1884. The general and local indications called for a repetition of the calomel and nitre, so that the prescription of the 29th of September was used again in the same form, with a moderate effect upon the bowels, and with evident relief to the symptoms of derangement in the biliary and urinary functions, and subsidence of the local swellings.

During three days there had been no febrile excitement, but now there was marked pain throughout the right lumbar region extending down towards the inguinal, through the iliac fossa of that side, and accompanied by considerable retraction of the lower extremity of the same side, with restlessness at night, so that an anodyne was given.

℞. Sulphate of morphia, 1 grain.
Sugar of milk, 12 grains.
Mix and divide in two powders. Give one, and in case he does not sleep within two hours the other may be taken.

October 3. Found that both portions of the morphia had been required to secure rest the night previous. The buchu mixture was resumed internally, and the belladonna ointment, with addition of an equal quantity of mercurial ointment was rubbed into the right lumbar and iliac regions, with a warm flaxseed poultice applied over this space continuously. The same prescription of morphia ordered for the night as on yesterday.

October 4. Both powders of morphia were required to allay pain and procure sleep. Continued treatment of previous day, including the anodyne.

October 5. A mitigation of suffering was apparent, but with impairment of the general strength, and deep-seated tenderness upon pressure in the iliac fossa, with restlessness at night, demanding both portions of the morphia to secure sleep, which came on only after midnight. The following formula was ordered to be prepared:

℞. Infusion of cinchona bark, serpentaria and cinnamon, tempered with elixir (antefebrile mixture of Lewis), 1 pound.
Chlorate of potash, 2 drachms.
Mix, and take half a wine-glass every two hours.

And for external application to iliac region:

℞. Collodion, 1 ounce.
Tincture of iodine, 2 drachms.
Camphor, 1 drachm.
Mix and apply with camel's-hair pencil night and morning continuously.

The sulphate of morphia was directed to be taken at a single time, in the dose of one grain at 9 o'clock p. m.

October 6. Without changing the treatment in other respects, the addition of spirits of turpentine was made on account of a slight tympanitic distention of the abdomen, giving one of the "Parvles d' Essence d' Terbinthine du Clertan" every two hours, along with the mixture of bark, etc., and a grain of morphia at night. This course was kept up for two days without any material change in the symptoms, excepting loss of appetite; and milk was the only article he relished as food.

October 8. With a view to a tonic and alterative influence, Fellows' syrup of hypophosphites was directed, in the dose of a tablespoonful every three hours; and finding that the deep-seated inflammatory action indicated the development of a psoas abscess; the collodion coating was discontinued, while camphorated mercurial ointment, with flaxseed poultices, was ordered over the space within the crest of the ileum, and extending

from the lumbar to the iliac, and down to the inguinal region, to be kept up from day to day.

October 9. To counteract a general tympanitic distention of the abdomen, and relieve the pain extending down the right thigh, this liniment was applied:

℞. Spirits of turpentine,
Olive oil, āā 2 ounces.
Camphor, 2 drachms.

Mix, and rub over the parts twice a day, leaving a flannel compress over the bowels.

The dose of morphine at night was reduced to a half-grain, but without inducing sleep until the latter part of the night, and was kept up thus. This general course, with the syrup of hypophosphites internally, the ointment and poultices over the iliac fossa, with the embrocation of spts. of turpentine to the lower bowels and the thigh, was observed for several days. But observing that there was an increased excitability of the nervous system with the further diminution of the anodyne, it was thought expedient to resort to another nervine preparation in place of the morphine.

October 13. This formula was ordered:

℞. Bromide of potash, 2 drachms.
Chloral hydrate, 1 drachm.
Elixir, 2 ounces.
Water, 4 ounces.

Mix, and take a tablespoonful every two hours at night until rest is secured.

Enemata were resorted to occasionally to move the bowels.

October 14. The effect of the repeated doses of the mixture taken last night was not satisfactory, as it had no soothing influence upon the patient, and it was therefore resolved to resort again to the sulphate of morphia in doses of ¼ grain at night.

October 15. There was copious vomiting on several occasions this morning, which was attributed to the disturbance of the digestive functions from the preparation of bromide of potash and hydrat. chloral; and I prescribed that good stomachic, old sherry wine, to be taken in portions of a half a wineglass every two or three hours, in connection with light nourishment.

October 16. As the stomach was still disordered with indications of acidity, my favorite corrective for this class of troubles was resorted to, with a happy effect in arresting the nausea and vomiting:

℞. Lime water, 3 ounces.
Camphor water, 2 ounces.
Peppermint water, 1 ounce.

Mix, and take a tablespoonful every hour.

From this time there was comparative relief from suffering, yet with the gradual development of a fluctuating prominence within the crest of the ileum, which was diagnosed as psoas abscess, and the poultices were assiduously applied, with a view to invite the purulent collection to the surface, so as to be discharged at an early day.

October 20. Dr. J. P. Logan was invited to see ths case with me, and upon examination he confirmed my judgment of the nature of the case; so that I proceeded to make an opening with a thumb-lancet into the softest and most salient part, midway between the point of the last rib on the right side and the crest of the ileum. A fine discharge of pus followed the withdrawal of the lancet through the orifice which corresponded to its breadth, and a drainage-tube was then introduced, extending some eight inches forwards and downwards within the sheath of the psoas muscle. It should be stated that there was no evidence at that time of the extension of the abscess posteriorly, and consequently there was no drainage indicated except in the direction of Poupart's ligament.

October 22. The following tonic was prescribed:

℞. Decoction of Peruvian bark, 1 quart.
Strong sulphuric acid, 1 drachm.

Mix and take half a wine-glass every three hours.

Generous living was recommended, including beefsteak and soft eggs, with milk punch. The discharge was profuse around and through the drainage-tube, and great relief was felt in all respects, excepting a sense of weakness and evident emaciation from the continuous drain.

October 26. The following record appears in my note-book:

℞. Sulphate of morphine, 1 grain.
Sugar of milk, 30 grains.

Mix and divide into four powders. Take one at night.

The anodyne had been gradually reduced to the dose of ⅛ of a grain for the twenty-four hours, and this sufficed to give him rest at night. Three drops of tincture nux vomica, with half a glass of port wine, was given every three hours in the day.

After the application of poultices were discontinued, owing to the gradual diminution of the discharge, compression was used over the surface, with a view to approximate the walls of the abscess, and the drainage-tube was discontinued. At this time a coating of the entire surface with the collodion mixture was resumed, and kept up until all discharge ceased.

In the meantime, there were indications of trouble in the deep-seated tissues of the lumbar

regions, posterior to the opening, but no signs of any discharge from that direction; and diurnal fevers, with slight rigor at the commencement, and followed by sweating, came on usually after midday, so that my colleague, Dr. J. P. Logan, was again invited to see the case with me on account of the constitutional disturbance.

October 30. Upon consultation, we concluded that most probably the developing abscess near the lumbar vertebra gave origin to the paroxysms as they corresponded to the stages of hectic fever; but in the event that there was any malarial complication from previous contamination of the system, the same kind of medication was calculated to combat either, so that we concluded to use the following prescription:

℞. Sulphate of quinine, 30 grains.

Divide in six capsules, and take one every two hours until four are taken to-day, and two remaining, with a like interval, to-morrow morning.

Afterwards, he continued to take five grains of the sulphate of quinine, twice in the morning for two days, and once for two other days, with almost complete relief to the paroxysms.

November 4. Finding that some fever appeared each afternoon, I ordered as a corrective, the following:

℞. Salicylate of soda, 2 drachms.
Iodide of potash, 1 drachm.
Fluid extract of jaborandi, 6 ounces.

Mix, and take a teaspoonful every three hours.

November 8. The periodical exacerbations having disappeared, he resumed the use of Fellows' syrup of hypophosphites.

Observing that the accumulations in the lumbar region caused some protuberance with evident fluctuations, and that no discharge from this source found an outlet at the orifice, which was still open, it occurred to me that another incision would be requisite immediately over the abscess. Accordingly, poulticing was kept up over this region for some days, and the presence of Dr. Logan was again requested to deliberate upon the proper mode of proceeding.

November 9. We met according to appointment, but greatly to our relief found that the purulent collection had passed out during the night at the original opening, so that no further incision was requisite. After poulticing over the entire surface, extending from the region of the lowest rib to the sacro-iliac junction, a compress was kept bound firmly over this space for some days, and subsequently the collodion, iodine, and camphor coating was kept constantly over this region, thus obliterating the cavity of the abscess by the agglutination of its walls.

November 12. The tendency to hectic passed away with the free evacuation of the pus, and the chief indication being to restore the strength, the patient was allowed the most nutritious food, with brown stout, and was directed to take the following tonic:

℞. Muriated tincture of iron, 1 ounce.
Tincture of nux vomica, 1 drachm.

Mix, and take twenty drops with a little sweetened water every three hours.

The ⅛-grain dose of morphine was only continued for a few nights.

November 16. Having dispensed with the use of morphine entirely, the French coca wine of Marini, prepared by Dr. J. L. Pemberton, of this city, was directed to be taken every three or four hours each day, in connection with the tincture of iron and nux vomica, and with decided good effect.

He progressed rapidly to convalescence, and at the close of the month of November was able to be about the room, and was gaining flesh as well as strength; so that early in December he left the city. A letter was received from him about the middle of the last-named month, reporting favorably in every respect, thus giving assurance of the complete cure of a well-developed case of psoas abscess within two months.

While the general treatment detailed was certainly advantageous in correcting the secretions and in supporting the powers of the organism under the exhaustive drain from the purulent collection, yet much of the good result is attributable to the local measures, in the prompt evacuation of the abscess, and the use of compression and counter-irritation for the obliteration of the cavity, developed first in the lower or anterior portion of the sheath of the psoas muscle, and afterwards in the posterior or upper portion, approximating the lumbar vertebra.

Under the conviction that this happy issue of my medical and surgical management in an aggravated complication of constitutional and local disorders, culminating in psoas abscess, may be worthy consideration by those having to treat similar cases, these clinical notes are submitted to the careful attention of my colleagues.

THE INCANDESCENT ELECTRIC LIGHT FOR THE EXAMINATION OF THE THROAT, NOSE, EYE, AND EAR; AN ELECTRIC OPHTHALMOSCOPE.

BY LOUIS J. LAUTENBACH, M. D.,
Of Philadelphia.

My experience with various kinds of lights has been derived from the examination of the throat,

nose, eye, and ear; as applied to other portions of the human body, I will not pretend to speak. In the present paper, I desire to call attention to the advantages of the incandescent electric lamp in the exploration of the parts before mentioned, but particularly in examination of the eye-ground.

Since the employment of the reflecting mirror, the illumination of the various parts of the human body, by means of artificial light, has been continually under discussion. As sources of light, the wax-candle, the oil-lamp, the gas-burner, the lime and electric light, have each been used. These lights have been modified in numerous ways to obtain the maximum brilliancy, the least yellowness, and to concentrate the light. The first was obtained by consuming a larger amount of material by means of an increase in the surface of the burners, and by increasing the thoroughness of combustion. As a result, we have the Argand burner, the Siemens' lamp, the student lamp, and other round and broad burners. To overcome the yellowness of the rays, slips of blue-glass have been interposed between the source of light and the reflecting mirror. To concentrate the light, convex lenses have been employed, being placed so as to intercept the light falling on the reflecting mirror; as illustrations, we have the Mackenzie concentrator and the Tobold lamp.

The lamps devised, in which it has been sought to incorporate one or more of these advantages, have been quite numerous; one is particularly struck by the number which have been designed for ear examinations. The Argand burner, the student lamp, the Tobold lamp, with, perhaps, one or two others, are about all which have been saved from the general wreck; of course, the lime and electric lamps are not here considered, both being but in their infancy; the Siemens' light is also passed by, because, so far as I know, the manufacturers have no intention of making them sufficiently small to allow of their introduction into private houses.

It is well known that there are two kinds of electric light—the arc light and the incandescent light. The arc light is occasioned by the combustion usually of carbon at the positive pole and the carrying to the negative pole of unconsumed, but intensely-heated particles of carbon. The light is of great intensity, and is, in consequence, of a violet-white color; it is, however, unsteady, having a strong propensity to vary in brilliancy, even sometimes to the point of absolute extinction. The most important objection, however, is the intense heat occasioned; it is mainly because of this fact that it is unsuitable for medical examinations; the intensity and unsteadiness being, however, also factors in precluding its use.

Believing that it will be impossible, for the present at least, to use the arc-light successfully for the examinations of special organs, I will not bestow more attention upon it, and will, therefore, use the terms electric light and incandescent light synonymously.

In the incandescent lamp there is no combustion, the carbon filament, within as absolute a vacuum as is possible at the present day, becomes incandescent by reason of the resistance it offers to the passage of a current of electricity.

HISTORY OF THE INCANDESCENT LIGHT AS APPLIED TO THE SPECIAL ORGANS UNDER DISCUSSION.

So far as I have been able to discover, Bruck,* a dentist of Breslau, was the first to construct and use an incandescent lamp for the examination of human structures. His instrument was known as the diaphanoscope. It consisted of a coil of platinum wire placed in a glass tube surrounded by a column of water. This was followed by Gustave Trouvé's† polyscope, which was exhibited at Baden-Baden in 1879. This consisted of an unprotected platinum wire placed in front of a concave mirror. The objection to its use was its heat, which sometimes was sufficiently great to fuse the platinum. This was followed by Dr. Nitze's‡ instruments for the examination of the urethra, larynx, etc. Shortly after this, Dr. A. Wellington Adams‖ published an account of an electric laryngoscope, which consisted of the ordinary laryngeal mirror, on the handle of which was a concave mirror, in front of which was placed a spiral tube containing a platinum wire in a carbonic acid vacuum. This wire was rendered incandescent by means of a Ruhmkorff coil. He used this instrument for the larynx and posterior nares. He promised that the description of an electric otoscope, which he proposed exhibiting before the Colorado State Medical Society, May 19, 1880, would appear in the September number of *The Colorado State Medical Journal* and *Rocky Mountain Medical Review*, but I have not been able to find any reference to this article.

About this time, Josef Leiter§ constructed in-

§Beschreibung einer instrumente und apparate zur direk-

struments for the examination of the various organs. He made use of the light derived from an incandescent platinum wire; this was usually placed behind a window or ledge, to prevent contact with the structures under examination. The instrument was cooled by the circulation of water. It, however, was necessarily bulky, and was either too warm, or else the light was so dim that nothing could be seen.

A year or two later, Carl Seiler* began to use the reflected rays of the Edison incandescent light, which he must have considered of value, as he writes: "I have no doubt that in the near future, when electric lighting will have been adopted universally, as gas is now, electric-lamps for the laryngoscope will supplant all other sources of light, with the exception of sunlight."

On the 16th of April, 1883, the instrument of Dr. Paul Helot and G. Trouvé was presented to the French Academy.† The description was published shortly thereafter.‡ The instrument was known as the frontal electric photophore. It consisted of a metal cylinder attached to the ordinary head-band. Within the cylinder is a small incandescent lamp; back of the lamp is a concave reflector; anterior to it is a strong convex lens to concentrate the light. This instrument has been successfully employed by Dr. E. C. Baber‖ for the examination of the throat, nose, and ear. About this time, Simanovoski§ published a description of an electric laryngoscope, but as yet I have not been able to obtain a description of the instrument.

Dr. Carl Seiler¶ exhibited his electric laryngoscope before the Pennsylvania State Medical Society, May 16, 1884. It consists of the ordinary concave head mirror, with a bar attached to its lower edge. The incandescent lamp is placed on this bar; between the lamp and the mirror is placed a strong convex lens, while between the lamp and the patient there is a mica shield. Dr. S. S. Cohen** advises the use of the incandescent light in connection with the Mackenzie condenser.

Dr. Laurence Turnbull* exhibited the laryngoscope of Dr. Starr† before the Philadelphia County Medical Society, October 22, 1884. It consists of an incandescent lamp, placed in a hollow cylinder of rubber, to the end of which cylinder the laryngeal mirror is attached. It is the object of this instrument to illuminate the parts under examination by means of direct rays of light. A very important measure incorporated in this instrument is a method of regulating the current, and thus regulating the illumination.

The objection to all instruments employing an incandescent platinum wire is that to obtain sufficient light the heat generated is so great as to fuse the wire. In Bruck's instrument its size debarred its employment except for oral examination; Nitze's instruments were too large for practical use; in Leiter's instruments, the two essential water-pipes made them too bulky; in Adams' laryngoscope the light was apparently too poor. Trouvé's frontal photophore is a very servicable instrument. Dr. Seiler's instrument is practically but the photophore placed in front of the head mirror; its disadvantage is its weight. The disadvantages of the Starr instrument are the slight heat occasioned and the fact that the eye is not thoroughly protected from the light.

Up to the present time, the incandescent light has apparently not been employed for the examination of the eye. Dr. Seiler,‡ speaking of his electric laryngoscope, writes that "it may be used for the examination of the eye," but does does not appear to have so employed it. I have been using the electric light for this purpose for a period of more than five months.

AN ELECTRIC OPHTHALMOSCOPE.

As will be indicated later on, I have employed the incandescent lamp in the ordinary situation of the gas stand, also within a Tobold condenser, as well as attached directly to the ophthalmoscope, employing the light with plane and concave mirrors, the latter of from three to fifteen inches focal distance. The method which has been of the most service where small lights only could be employed, was that adopted in the instrument here figured. Fig. 1 is $\frac{3}{4}$ natural size, Fig. 2 being the exact size of the lamp.

It consists of an ordinary Hunter's Loring swinging mirror ophthalmoscope, to which is sol-

ten Beleuchtung menschlicher Körperhöhlen durch elektrisches Glühlicht, Wien 1880; also, Annals of Anatomy and Surgery, vol. vii., 1883, p. 129.

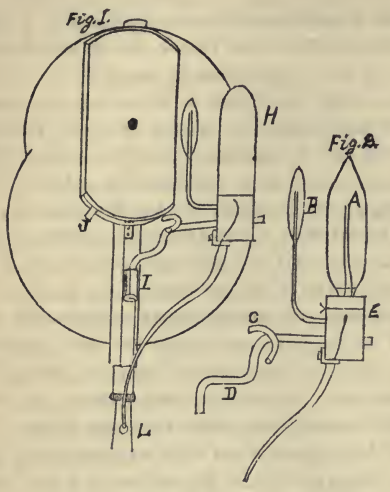
dered the slot I, fitting into this slot is the arm D, which carries upon it a hard rubber cylinder,



E, which can be slid down closer to the mirror if desirable; this rubber cylinder carries upon its upper extremity the incandescent lamp A, over which is fitted the asbestos (non-conductor of heat) cap H, between which and the posterior surface of the lamp is the reflector. Fitting into the rubber base, E, is a wire carrying the biconvex lens B of $\frac{3}{4}$ inch focus. The lens can be approached to the light at will. It should, however, be placed at about half an inch from the filament. On the bar D is a cross-bar C, the ends of which strike against the projections of the swinging mirror J. This bar is of such length on either side as to place the lamp at an angle of 60°, with the general plane of the mirror: by this device, the swinging mirror is placed in position for one or the other eye, by adjusting the lamp for the same eye. The wires are carried from the hard-rubber piece either down to an opening L, entering a hollow fixed handle, or to a ring which slides easily about the lower end of the handle: this latter device allows of the ready detachment of the handle. Two asbestos caps are employed: in one the light makes its exit through a small round opening; in the other, which is only used occasionally, the opening is a vertical slit. The convex lens concentrates the light and renders it almost parallel. I have employed the plane reflecting surface in connection with this lamp, but have not found it as satisfactory. A concave reflector with a focal distance of three inches, I used without benefit. If the amount of light obtained in the eye is more than the observer desires, it is only necessary to revolve the lens B out of the field of light.

* * * * * * * *

This light will prove of advantage in the examination of the dark complected; whenever there is a small pupil; of myopics—in all of these cases giving us better illumination than we can obtain by other means. It will be of service in atrophic nerve cases, but its advantages are particularly marked in slight retinal inflammations, and for the study of the retinal circulation. Because of its intensity, it will allow us to make more thorough ophthalmoscopic examinations in cases of corneal, lens and vitreous opacities.

(*To be continued.*)

Hospital Reports.

NEW YORK HOSPITAL.

CLINIC OF PROF. WILLIAM H. DRAPER, M. D.

Reported by W. H. Seelye, A. M., M. D.

Transverse Myelitis.

This is the patient you saw the other day with a myelitis, (see page 268), and at that time there was loss of sensibility in all the parts below a line drawn across the abdomen, at the level of the umbilicus. This line of anæsthesia has not changed much since, but it appears to have risen a little higher. You observe that the place where a mustard plaster had been applied upon the abdomen, and the skin had peeled off, has healed over and new skin formed. There seems to be some tendency to sloughing, however, over the tuber ischii as the result of blistering with mustard, and it is not healing very well. But there is not any evidence of deep sloughing. The water still has to be drawn with a catheter twice a day, and the bowels move involuntarily. This combination of symptoms is not infrequently seen, namely a retention of urine with loss of power over the sphincter ani.

This man has had a pretty high temperature since you saw him. It is as high as 104.4° today, and most of the time it has ranged above 104°. Yesterday morning it was 100.4°, but it rose again in the evening. His breathing is now pretty rapid, and his face is flushed, and his hands are cold, and his expectoration is bloody, and the blood is in streaks, and it evidently comes from the lungs. The condition of the face and hands seems to indicate that the rapidity of the respirations is due to the presence of some pulmonary congestion. The other day I told you that the case might prove to be one of polio-myelitis of the anterior horns of gray matter, and not a myelitis affecting the whole cord; and I then told you that in polio-myelitis confined to the anterior horns, there is sometimes as much disturbance at the beginning as there was here. But the disturbances of sensation and the vesicle spasm disappear after a few days, leaving a loss of power only in the affected muscles, which is more or less complete. But here the loss of power

in the lower extremeties continues obstinately, and the muscles give no response to the faradaic current, and the vesical and rectal paralysis continues, and the disturbance of sensation seems to be spreading, and there is pulmonary congestion which may be due to a diminished power in the respiratory muscles; and so I now think that we have to deal here with a transverse ascending myelitis. There are signs also of a condensation, but not very marked, at the lower portion of the lungs posteriorly. This probably depends upon hypostatic congestion, rather than upon muscular weakness and diminished respiratory action.

Convulsions.

The man whom you saw last Thursday in convulsions, went out of the hospital yesterday. He had, on the evening of that day, two or three convulsions, which were very violent. But after that he made a good recovery. Very little information could be gotten from the man; he was a tramp. But he said that he had not had any such attacks before, and that the attack in which you saw him had been preceded by some indulgence. He went out in the morning, and remembered nothing after that. Now this abolition of memory in attacks of epilepsy is a very striking feature; though not an absolutely constant one; for in some instances the patient is shut off by an attack in the midst of some special utterance, and then after the seizure has passed off he resumes the sentence at the point where he was interrupted as if nothing had happened. But this is not very common. After a grand attack the memory is usually obliterated for preceding events which happened some hours before. Such was the case with this man, who was brought into the hospital about 2 o'clock p. m., and whether he was drunk or not previously is not known; but I am inclined to think that these convulsions were alcoholic in nature.

About a year ago a man came in here who had taken a large dose of chloral, and in twenty-four hours after his admission he had a number of convulsions quite as severe as those you saw in this man, and they lasted several hours, and were most violent in character. He was bled with no advantage, and he finally died. The post-mortem inspection showed no lesion within the brain, however. And had this man succumbed, probably his brain would have shown no lesion.

We frequently have here such cases of epilepsy as the result of alcoholism, but that was a case of special interest because it illustrated the difficulties which sometimes stare you in the face when you have to determine immediately the cause of an epileptic attack. In this case we fully excluded true epilepsy and apoplexy; and while the absence of albumen from the urine does not necessarily exclude uræmia, yet it seems that here the convulsions were not uræmic. So by a process of exclusion we are brought down to blood-poisoning, from something absorbed in the circulation as a cause; such as chloral poisoning in the former case, but alcoholism here.

—Spurious cubebs have recently been offered in the London market. They consist of the fruit of *Daphnidium cubeba*, which closely resembles cubebs in general appearance.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Thursday, February 5, 1885. The president, B. F. Baer, M. D., in the chair.

Cervical Pregnancy.

Dr. E. E. Montgomery read a paper in which he recounted the history of a case seen by him in consultation with Dr. Alexander. The patient had been pregnant eight times; the last labor had been terminated by forceps. The present pregnancy had lasted three months when she was taken with severe pain and quite profuse hemorrhage. An examination under ether disclosed that the cervix was distended forming a globular tumor. The os, turned backward, was filled up with a tense membrane; breaking through it, the cervix was found to be a large cavity in which was the fœtus and its envelopes. The body of the uterus appeared like an excrescence upon the distended cervix; it would admit a finger and was lined by a decidua. The membrane below was continuous with the outer mucous membrane of the cervix, so that the remains of it hung as a fringe from the os.

This case differed from the few cases of this condition described, in that there was no contraction of the os; in the majority of cases it occurs in primiparæ and when discovered it was necessary to proceed to artificial measures to make an opening.

Dr. Goodell remarked that he had no knowledge of cervical pregnancy. One case which had been sent to him as such was epithelial cancer of the cervix. How could such a case be diagnosticated without a post-mortem examination? Dr. Montgomery's hypothesis of an arrested abortion is probably the correct solution of such a case as he has described. The fœtus might be forced out of the body of the uterus and arrested in the cervix by an unyielding os or by cicatricial bands. Some years ago, a physician of this city who had a large obstetrical practice, borrowed his ecraseur for the removal of a supposed uterine polypus, which proved to be a fœtus in its amniotic sac. Dr. Goodell had never been able to understand how an experienced man could make such a mistake, but the description of this case of cervical pregnancy has thrown light upon the matter. Dr. Montgomery's description of the distended cervix would apply very well to uterine polypus with a long pedicle, and a mistake in diagnosis might easily be made.

Dr. Montgomery questions the primary occurrence of cervical pregnancy. He believes the fœtus has originally taken its seat in the body of the uterus, and has been forced into its lower position later; but it might be primary, the internal os being patulous, the same conditions that sometimes cause placenta prævia might cause the entire fecundated ovum to be arrested in the cervix.

Ruptured Uterus.

Dr. B. F. Baer presented the specimens and related the history. Mrs. F., colored, 32 years of age, married ten years, had borne four children at term, and had one miscarriage. The first child

was forceps-delivered and was still-born. November 14, 1884, she was taken in labor. A midwife was in attendance, who pronounced everything correct. After a few hours of severe pains, the patient "felt something break in the womb" and labor ceased, but was replaced with sharp pains all over the abdomen. Blood escaped in great quantity from the vagina. Collapse ensued, and she was thought to be dead; a slow reaction occurred, and her attendants waited for labor to begin again. Dr. Fisher was called to see her ten days after the accident. He found her abdomen tender and tympanitic, a mass like the head of a fœtus in the right hypochondriac region. The pelvis was empty. Temperature 103°, pulse 108 and small. Rupture of the uterus, and escape of the fœtus into the abdominal cavity, was diagnosticated. Dr Baer was called in and confirmed the diagnosis. The patient refused operative assistance, and preferred to die in peace, but five days later asked to be relieved. Preparations were made for laparotomy. An examination per vaginam revealed a gangrenous pus escaping freely, and the placenta loose and hanging from the vagina. The hand passed readily through the os uteri and through a tear in the right wall of the cervix into the abdominal cavity, and came upon the trunk of the child. The latter was extracted through the vagina by version by the feet; it was putrid. The parts were well irrigated with carbolized water, and the hand, again introduced, entered an adventitious sac, and nowhere came in contact with intestines or other viscera. The uterus was well contracted and quite small. The uterus and sac were washed out with carbolized water until it returned pure. The patient died of septicæmia ten days after the removal of the fœtus. Dr. Baer is in full accord with the principles advanced by Dr. R. P. Harris in his paper, entitled "If a woman has ruptured her uterus during labor, what should be done to save her life?"—*American Journal of Obstetrics*, Oct., 1880, p. 809, in which he advises that the abdomen should be opened and the peritoneal cavity thoroughly cleansed. In this case, however, nature had protected herself by forming an adventitious cavity, and there could be no reason to open the abdomen to clean this out, as it could be reached from below more directly and without injury to the soft parts.

Dr. Henry M. Fisher: In Germany a distinction is made between lymphatic septicæmia and phlebitic septicæmia. In the first form the poison is absorbed by the lymphatics, and inflammation of serous surfaces with exudation is the consequence. In the phlebitic form, numerous emboli are formed and hectic fever and local pus formations, the result of these emboli, are found. At the autopsy, in this case, pleural and pericardial effusion was found. It will be remembered that peritonitis occurred very soon after the rupture.

Dr. Goodell remarked that he had come intending to criticise Dr. Baer's treatment of this case for not resorting to laparotomy, but he found himself agreeing with both Dr. Harris and Dr. Baer. In recent cases laparotomy should always be performed, but in fifteen days an adventitious sac had been formed, and the dangers to the patient would have been increased by operation. He had seen two cases of rupture of the uterus, both of them occurred in the practice of a physician who never used obstetric forceps, and had to send four miles for a consultant. in the first case peritonitis rapidly supervened, the abdomen became very much enlarged, and the fœtus could not be located by palpation. The abdomen was not opened. After long groping, the fœtus was found close under the diaphragm. He had great difficulty in extracting it, as the loops of intestines became entangled between its legs; the placenta was also found in the abdomen. In the other case, the body of the fœtus had escaped into the abdomen, but the head was still in the uterine cavity; it was delivered by forceps. Both patients died. In both cases it would have been far better to have opened the abdomen. *American Journal of Obstetrics*, vol. x., 1877, p. 478.

Dr. Harris is in accord with Drs. Goodell and Baer as to the proper treatment of the case reported. It was too late to do anything when the physician was called. The general opinion is coming around to coincide with his way of thinking concerning the propriety of laparotomy in all cases as soon as reaction from the shock of rupture and hemorrhage has been established. Of the cases reported, after such treatment, 50 per cent. have recovered. One woman has been reported as having ruptured her uterus in four successive labors, with delivery per vaginam and without laparotomy, and she survived it all; but such a case is phenomenal. Three cases in Europe have been treated by removal of the uterus as in the Porro operation: they all died. There seemed to be no reason for such a method. In most cases the split extends through the cervix, and thus free drainage from the abdominal cavity is secured. One reason for closing the cervical rent by sutures is to avoid the danger of cancerous growths to which that lesion is supposed to give rise.

Dr. Longaker remarked that many of these cases died from the profound shock and hemorrhage immediately following the accident. Two cases in his experience had died within two hours, one of them undelivered.

Dr. Baer was glad to hear Dr. Harris make the distinction as to the propriety of laparotomy in his case, where the patient was not seen until fifteen days after the accident and was suffering from septicæmia. He had intended to perform laparotomy, and was prepared for it; but when he found the newly-developed sac he changed his plan, as he thought nothing could be gained by it.

Ovarian Cysts.

Dr. Baer exhibited two ovarian cysts. Mrs. B., widow, entered my private hospital, December 18, 1884. She commenced eight months before to suffer from frequent calls for micturition with severe scalding pains, symptoms apparently of cystitis and urethritis. The uterus and ovaries were in good position and seemed normal, but two weeks later there was a burning pain in both ovarian regions with a perceptible bulging largest on the right side. The menses had ceased, and the doctor in attendance suspected pregnancy, but exposure was denied at that time. The abdomen enlarged rapidly, and the patient finally acknowledged the possibility of pregnancy, and

thought she felt movements of the fœtus. At seven months, uterine hemorrhages commenced and continued every day; the mammæ were atrophied; there were no signs of the presence of a fœtus; there was some fluctuation; the sound was passed, and the uterus was found empty and not enlarged; the face was wasted, and had an anxious expression, and the pulse was quick. A diagnosis of ovarian cyst was now made. A deep diagonal sulcus could be made out in the abdominal tumor, the largest portion being on the right side; the tumor was smooth-surfaced and without nodules. The cervix was soft, patulous, high up, and drawn to the left. When the tumor was moved the uterus moved with it, as shown by the handle of the sound. Immediate operation was advised and performed. Incision, three and one-fourth inches. Two large tumors were revealed; both were tapped; the left, which was free from adhesions, was withdrawn without difficulty, its pedicle transfixed, ligated, and dropped. The larger tumor, although free from abdominal adhesions, could not be drawn out, and it was found to be very tightly adherent to the uterus, which seemed to be one mass with it. As the fluid drawn from this tumor was clear, it is not improbable that it was a cyst of the broad ligament. It became necessary to enucleate the cyst, and a long, gaping wound was left in the broad ligament; this was transfixed and tied as a pedicle, but after the final division had been made, the ligature slipped and the hemorrhage was immense; ten hemostatic forceps were applied temporarily, and the bleeding points were firmly secured. The wound of the broad ligament was closed by ten interrupted sutures. The operation lasted two and a half hours; the patient collapsed, and he feared she would die on the table; but she reacted and recovery was uninterrupted; the patient sat up in two weeks. An incident, which occurred on the fourth day, shows the necessity of the proximity of a physician or thoughtful nurse. A scream from the patient—an announcement of a sudden pain on the right side—the patient said something seemed pulling inside of her; Dr. Baer was near and was called; he feared internal hemorrhage, but at once inquired how long it had been since she had passed water—four hours; the catheter was immediately used, and complete relief was secured. After this the catheter was not required until the tenth day; but from the tenth to the twentieth day there was entire inability to pass water, except by assistance of the catheter. She went home on the twenty-third day.

The points of special interest in this case are:

1. The patient being entirely well, symptoms of gonorrhœa presented themselves, and were followed by
2. Amenorrhœa for seven months, followed by
3. Daily hemorrhages for one and a half months.
4. Ovaritis and large tumors forming in eight and a half months from the initial symptoms.

Dr. Beates: A young lady was obliged to separate from her husband one month after marriage, in consequence of domestic trouble; her menses continued regular, but her abdomen enlarged as rapidly as if she were pregnant, her health failed, and at the expiration of nine months an ovarian tumor was removed; recovery was complete and rapid.

In another case he found numerous omental and enteric adhesions which were easily separated, but pelvic adhesions required enucleation of the cyst, which left a large V-shaped wound in the broad ligament, as described by Dr. Baer. Hemorrhage was very free; in trying to dissect off the tumor from the fundus of the uterus, that organ was badly wounded, the cavity was opened, and required to be closed by sutures. Great tympany followed this operation, and breathing became almost impossible; the patient recovered.

Calculi in the Female.

Dr. J. W. Snowden exhibited the stones and related the history of the case. He was called June 1, 1884, to see Mrs. L., aged 23 years. She was born and has resided in a limestone region in New York. Up to thirteen years of age she was troubled with eneuresis; wetting the bed almost nightly. After this she ceased passing her urine during sleep, but was obliged to rise for this purpose two or three times during the night. She could not retain her urine night or day after the desire to pass it came on. If she could not reach a convenient place, she would wet her clothes.

She married when seventeen years old. Two months after marriage she began to have cystic irritation, and soon passed sabulous matter and small calculi. These symptoms continuously increased. Physicians whom she consulted said she had catarrh of the bladder, but none made an examination for stone. Once she was obliged to call on a medical man to remove a calculus which had become impacted in the urethra.

Two years ago she spent a summer in New Jersey, during which time she passed no gravel, but the irritation of the bladder continued. When I first saw her she was urinating very frequently, with more or less pain. She passed stones daily, with a great deal of sabulous matter. The urine looked as if there was a quantity of ordinary sand in the bottom of the vessel. I proposed an examination for stone, which she refused peremptorily. I gave her benzoic acid, which entirely stopped the passage of the sabulous matter, and relieved her in every way; but she still occasionally passed a small calculus. This marked relief lasted two or three months, when the irritation of the bladder became worse than ever. She could only pass her urine in the erect position, and with as much effort as a woman in labor. I insisted upon an examination for stone, but the slightest touch excited such pain, even when she was well etherized, that being alone I could not manage her, and I sent for Dr. B. F. Baer in consultation.

A calculus measuring about one and a half inches in its largest diameter was found in the bladder, and removed by Dr. Baer after rapid dilatation of the urethra. This afforded marked relief, and she soon seemed entirely cured; but in a short time her urine began to dribble continually while she was in the recumbent position at night. During the day she retained and passed her urine naturally. I advised her to get up at stated intervals and empty her bladder, which has gradually relieved this trouble. She is now quite well, except that she urinates rather more frequently than is natural.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated meeting January 26, 1885. The president, Dr. S. Weir Mitchell, M. D., in the chair.

Dr. H. C. Wood presented to the Society

The Feet of an Ataxic Patient Illustrating Charcot's Joints.

The specimens were from the Mütter Museum of the College of Physicians, the feet of an ataxic patient that had been under his care at the University hospital. He expressed the opinion that there was a close relation between this disease of the bones in ataxic cases and syphilis.

A paper was read by invitation, on

The Spinal Arthropathies.

A clinical report of six cases of Charcot's joints, by A. Sidney Roberts, M. D., surgeon to the Philadelphia Hospital, instructor in orthopœdic surgery in the medical department of the University of Pennsylvania.

Case 1. M. K., male, æt. 41, referred to the New York Orthopœdic Dispensary from St. Luke's Hospital on May 5, 1879. Hereditary history unusually good. He is a moderate drinker. Health excellent until manifestation of present joint trouble. Married, and the father of five healthy children.

Condition on date of entry: A large nodular tumor was found over the left hip-joint, oval in shape, the long axis of which corresponds with line of Poupart's ligament. Transverse diameter of normal limb over hip-joint, 22 inches; of affected limb at same point, $30\frac{1}{4}$ inches. No muscular atrophy detected by measurements of circumference. Left limb $1\frac{3}{8}$ inches shorter than its fellow; measurements made from the umbilicus. External iliac fossa of left side filled with osteophytes, which add to bulk of tumor. The ligamentous structures about the joint seem entirely destroyed; motion of limb abnormally free in all directions. Head of femur probably absorbed or greatly atrophied. Limb abducted and rotated outward. What appears as the head of the femur is anterior to its normal position, lying under a "shed" of bone, built out from the pelvis, which covers its atrophied extremity like an umbrella. When the patient flexes the limb, the upper extremity of the femur glides forward until it catches under this shed of provisional bone, which, acting as a fulcrum, allows the patient to flex and rotate the limb with ease.

A thorough examination of the patient for evidence of a central lesion, revealed the absence of numbness of limbs, of pain, or of constricting bands; sensation slightly impaired on left side. On right side, reflex action increased on titillation of soles; none on left. No tendon reflex in either limb. Sways with "closed eyes test."

Condition eighteen months later: The patient presented all the marked symptoms of locomotor ataxia. Two years from date, upon which the above notes were recorded (May 5, 1879), he is confined to bed, with complete loss of muscular coördination.

Remarks.—The case exhibits an arthropathy existing four and a half years prior to the development of active tabetic symptoms, and shows a tendency, from early stages, to the formation of osteophytes about the joint, with early atrophy of the upper epiphysis of the femur.

At no time during the progress of the lesion were there developed reflex neural symptoms that would point to joint inflammation.

The joint lesion (swelling and tumefaction) diminished as the active symptoms of ataxia advanced. Provisional callus was thrown out about the atrophied extremity of the femur as a substitute for the destroyed acetabulum.

Case 2. Male, æt. 44. Registered as an outpatient in the New York Orthopœdic Dispensary on January 29, 1879. The following notes were recorded:

Hereditary History.—Parents living and healthy; one brother died of phthisis. Patient is married; has three children, two in excellent health, the third has an intra-pelvic abscess. (Subsequently died of amyloid degeneration of the kidneys.) Patient has had to work very hard, with considerable mental anxiety; no other known cause for present disease.

The left knee and ankle are enlarged, the latter more so relatively than the knee. The patient states that seven years ago, while working, a heavy box fell upon him, injuring the ankle. The joint became swollen, and he was "laid up for two months." He recovered, and suffered no inconvenience for one year; the swelling again returned in the same ankle and involved the entire leg. At this time he was incapacitated from work for three months; he recovered, and has had no active joint symptoms since. Has never had an abscess about the joint.

The urgent symptoms at present examination are those of locomotor ataxia. He cannot walk without staggering, and when attempting to do so in the dark, or with closed eyes, falls. Suffers from ataxic pains in the right leg and arm. Is uncertain in guiding his finger to the tip of his nose, with closed eyes, or in putting his heel on a designated spot. Sensation impaired in right hand and arm; has difficulty in buttoning his coat with that hand. When standing, or walking in his bare feet, he feels as though he were on cushions; vision unimpaired (eye-ground not examined).

On February 4, 1879, Dr. Cloves Adams saw the patient in consultation, and thought him to be suffering from locomotor ataxia in the third stage, with osseous changes in left ankle and synovitis of both knees.

The patient returned to the dispensary in September of the same year, with a marked elastic swelling of the right elbow-joint.

A year later (November, 1880), he was referred to the clinic of Dr. E. C. Seguin. He again applied to the Orthopœdic Dispensary on February 14, 1881. The ataxic symptoms had advanced; he walked with extreme difficulty. The condition of the joints remained about the same as when last examined, now four months ago.

During November (1881) the patient was critically examined by Dr. S. Weir Mitchell, and pronounced to be in the third stage of locomotor ataxia, with spinal arthropathies of the right elbow and left ankle-joints. It was noted that the circumference of the elbow tumor had materially diminished since the last measurements were recorded (decrease of two and a half inches).

Remarks.—The joint enlargements in this patient presented three characteristic peripheral ataxic conditions:

1st. At the knee-joint synovial irritation, indicated by the physical signs of a chronic synovitis; although at no time during its course was there evidence of inflammation.

2d. A characteristic doughy, nodular ataxic joint tumor of the elbow, largely composed of osteophytes and excessive synovial secretion.

3d. Hypertrophy of the lower epiphysis of the tibia and fibula, with but slight synovial irritation.

The peripheral manifestations at the knee and ankle, accompanied the earlier symptoms of ataxia; the elbow tumor entered abruptly upon the second stage of the sclerosis. I am indebted to my friend Dr. Newton M. Shaffer, of New York, for the privilege of reporting the above notes.

Case 3. J. H., male, æt. 45; was admitted to my ward in the Philadelphia Hospital on April 3, 1883. The following notes were recorded: A vigorous, well-nourished man, with little personal knowledge of his family or their history. Knew his parents lived to advanced age, but thought both of his brothers had died, and likewise two sisters, when young. Acknowledged to being strongly addicted to the use of alcohol. He thought his present trouble arose from a "dissipated life and constitutional syphilis."

Two years ago, after a debauch, his attention was directed to painful swelling of his right great toe. This lasted a few days, and as the pain and swelling of the toe subsided, the right ankle-joint enlarged. This swelling slowly and painlessly increased, and three months from its onset, the same condition appeared in the left ankle-joint. Without especial discomfort to the patient, this joint enlarged. He continued drinking to excess, and was admitted to the hospital in a state of chronic alcoholism.

An examination two weeks after admission, when all traces of alcoholism had subsided, gave evidence by the following facts of a central lesion: He had suffered from constricting pains about the abdomen, and occasional darting pain in the region of the hips and thighs, for the past year. He also experiences considerable difficulty in walking, especially at night. At present, he has a staggering gait. Absence of patellar reflex in both limbs: sways and falls with "closed eyes test," and has difficulty in finding tip of nose with forefinger when eyes are closed.

The metatarso-phalangeal articulation of the right great toe is ankylosed. Both ankle-joints are enlarged apparently by a diffuse hypertrophy of the epiphyses of tibia and fibula. This increase has almost doubled their normal circumference. The subcutaneous tissues are slightly œdematous. The capsules of ankle-joints are distended and elastic.

When first admitted, the tissues about the ankles and legs were swollen, presenting the appearance of diffuse cellulitis. This subsided in a few days from rest and local treatment.

My colleague, Dr. C. K. Mills, saw the patient with me in consultation. and confirmed the diagnosis I had made—of posterior spinal sclerosis, with accompanying arthropathies at ankle-joints.

Remarks.—The joint hypertrophy had preceded any active symptoms of ataxia. The character of the joint enlargement was that of bony hypertrophy, without a tendency to the formation of osteophytes or to a nodular irregularity of contour. The possibility of rheumatism or malignant disease was considered and dismissed. A thorough physical examination failed to detect any of the characteristic reflex neural symptoms of an epiphyseal osteitis.

The history of the progress and course of the ankle-joint hypertrophy, together with the evidence of a central lesion and the negative physical signs of local joint inflammation, all confirmed the diagnosis of an arthropathy of spinal origin.

(*To be continued.*)

EDITORIAL DEPARTMENT.

PERISCOPE.

A Case of Cholera, Illustrating the Successful Effect of Precautionary Measures in Preventing the Spread of the Disease.

Dr. C. David, of Geneva, thus writes in the *Brit. Med. Jour.*, Jan'y 31, 1885: Mrs. X., 30 years of age, very much affected by her coachman's sudden death from cholera, left Marseilles on July 25th last, with all her family, in order to escape from the epidemic. She had been troubled with some slight diarrhœa, and her medical attendant had advised her not to remain at Marseilles.

She arrived at Geneva on July 27th, and proceeded at once, with her husband, to try to find an empty house. Thus she came to Versoix (a village at the lake-side, on the west shore, about five miles from Geneva), exhibiting at the time no external signs of disease. After visiting an empty villa in that place, she took it, and went back to Geneva for the night.

On July 28th, in the afternoon, she returned to Versoix with her family, consisting of eleven persons; and the owner of the villa, finding her looks much altered since the previous day, advised her to send for me.

I saw Mrs. X. half an hour after her arrival. She was still wearing her travelling dress, and had gone upstairs into a bedroom she was destined never to leave. During my visit she had several rice-water evacuations, was seized with vomiting, and complained of abdominal pains and cramps in the legs; temperature of the body 36.4° C.; there was much emaciation; she had a small and rapid pulse. This had every appearance of a case of cholera. As soon as I had quieted the patient with reference to police-measures, with which she was afraid to be troubled, and I had assured her she would not be taken by force to the hospital, she acknowledged she had been ill the whole of the night and previous day: the fear of the police had prevented her, so far, from calling in medical aid.

Drs. Girod and Prevost were called in consultation, but the disease terminated fatally. The diarrhœa and vomiting ceased during the night of the 29th–30th; the temperature rose in succession to 38° and 39° C.; she was unable to overcome her state of emaciation and weakness, and she died on the 30th at 2 p. m. Her intellect had remained unimpaired until the last few hours, when she fell into a state of stupor. There had been no passage of urine since the 27th, in the evening.

This is, to my knowledge, the only uncontested case which has occurred in Switzerland. It might have become, according to the views generally entertained at present, the origin of an epidemic focus; fortunately this did not happen. The following were the measures adopted by myself and my colleagues to prevent such an occurrence, which, thanks to local circumstances, were easily carried out. The villa, situated between the two villages of Versoix, is limited on one side by the high road from Geneva to Lausanne, and on the opposite side by the lake. It is at a distance of at least twenty-five métres from any other dwelling, and is screened off from the neighboring houses and high road by a number of trees. In front of it is a meadow, reaching as far as the lake. The place is entirely surrounded by hedges and walls, which enclose it without a break. An avenue through a shrubbery for a distance of 100 métres leads to the house, and there is a gatekeeper's lodge where the avenue branches off from the high road.

The patient's room was on the first floor, had no access into the other rooms, and communicated with the stair through a narrow passage.

Under such conditions, the precautions to be taken were obvious, and easy to carry out. It was necessary, as far as possible, to protect the members of the family and the servants, and prevent absolutely any contact between the people in the villa and the inhabitants of the village. As soon as the nature of the case had been ascertained, I had all the useless objects and furniture removed from the room; next, at my request, the head of the family selected the persons who would have the care of the patient. These were Mr. X., a male servant, a lady companion, and myself. The others were strictly ordered not to enter the sick-room. The dirty linen found in the lady's trunk was immediately immersed in a solution of two per thousand of corrosive sublimate, and left there for several days. The fæcal evacuations and vomited matters were received in vessels containing some of this same solution. They were afterwards transferred to another vessel, where they remained till the evening, when they were buried at a distance of two hundred steps from the house, in the meadow adjoining the lake. A certain amount of five per cent. carbolic acid solution, and two per thousand corrosive sublimate solution, was at the disposal of those persons who were engaged with the patient, and they used them abundantly.

With reference to the intercourse with the village, the inhabitants of the villa were ordered not to go out of the grounds. The tradesmen delivered their goods at the gatekeeper's lodge, who transmitted them to the servants. The dwellers at the lodge were not allowed to enter the villa, and the tradespeople never passed the lodge.

Nobody but the physicians and a priest went in and out of the villa, and these persons never left without having washed themselves with a solution of corrosive sublimate, and being subjected to powerful chlorine-fumigations from chloride of lime, mixed with sulphuric acid. In order to be absolutely correct, it should be stated that a young girl, with less discipline than wisdom, who had been engaged on the first day by Mr. X., made her escape from the villa during the night to sleep at her mother's, who lived in an isolated house; she returned the next morning, and did not go out again.

A sick-nurse, engaged on the 29th, and the mother and brother of the patient, arrived from Paris on the 30th, and were admitted into the house, after having been warned that they would not be allowed to go out.

Death having taken place on the 30th, at two o'clock, the physician at the head of the sanitary department of the Geneva Government, Dr. Vincent, was informed of the occurrence by telegraph, and ordered the body to be buried at once; this was done at seven o'clock in the evening, allowing barely time to procure a coffin and dig out a pit.

The body, enveloped in the clothes and portions of the bedding which had been in contact with it, was watered with disinfectants, placed in an oak coffin, and carried to the cemetery in a funeral carriage. All the other objects which had been used during the patient's illness—bedding, crockery, curtains, linen—were watered with disinfectants, buried in a second pit, and covered with quicklime. All this was done under direct medical supervision.

After the body had been taken away, the room which the patient had occupied was thoroughly fumigated with chlorine. Moreover, several litres of carbolic acid were thrown into the privies. The next day, Dr. Vincent proceeded to disinfect minutely the furniture with several "siphons" of liquid sulphurous acid, according to Raoul Pictet's process; and, somewhat later, the walls were washed with a five per cent. solution of carbolic acid. All the dirty clothes of the family were immersed for several hours in a bath of carbolic acid before being sent to the wash.

In accordance with an order from Dr. Castella, sent by the Federal Council, the family were not allowed out of the villa until August 9th, or ten days after the lady's death. As by that time no other case of cholera had occurred, either in or outside the house, the inmates were at last set at liberty.

Such were the measures taken to prevent the extension of the disease. I have no more to do than to wish for my brethren cases where precautionary measures are so obvious as to their nature, and so easy to carry out.

Dr. Marcet says: I happened to be staying close to the village of Versoix this summer, when the case, so well managed by Dr. David, took place. This village consists of two rows of houses, with the high road between them. It is a singular fact that Napoleon the 1st had intended to make Versoix into a large town, and had constructed a spacious harbor for it, but his views in this re-

spect were never carried out. The village remains divided into two portions along the lake, which were clearly intended to have been joined, and form the nucleus of the town. It is certainly not a clean village, and there are abundance of smells in the houses and shops; no doubt, the pabulum was there for an epidemic of cholera, if an opportunity offered. It cannot, therefore, be said that external circumstances were unfavorable to the disease spreading; and most probably, but for Dr. David's prompt and energetic measures, the disease would have broken out in the village.

I have a case in point, illustrating the effect of the neglect of precautionary measures towards checking the spread of cholera.

In October, 1866, I happened to be staying near the village of Nirnier, of perhaps five or six hundred inhabitants, situated on the Savoy Coast of the lake of Geneva. One evening I remained some time in conversation with a man I was employing, and who appeared to me then in perfect health. This man, after leaving me, went to sleep at Nirnier. Next morning I was informed that he was very ill, and I went to Nirnier to see him. I found him in a state of collapse, and it was at once clear to me that he had cholera; he died that same day about five o'clock. The story told at the time, and in which I believe, although I cannot find confirmation now, was that the man had eaten supper that same evening in company with a person who had left Marseilles on account of the cholera, and that this person had gone away early the following morning, without leaving any trace of his whereabouts.

I warned the mayor of the village at the time, and tried to convince him of the importance of removing the dunghills in the streets, whitewashing the houses, and using chloride of lime abundantly, but my warning was of no avail. There spread at once a report that the man had died poisoned by an overdose of certain pills he was then taking, and not of cholera. Two or three days later, an epidemic of cholera broke out in the village, and within about three weeks there were eleven fatal cases. The epidemic then suddenly ceased.

I made inquiries last summer at Nirnier, with reference to the cholera of 1866. Many have a very distinct recollection of it, and I obtained minute details from some women, such as the names of those who had died. The history of the epidemic having been imported from Marseilles is, however, ignored or disbelieved; and, unfortunately, the people who kept the public-house where my man had had supper after leaving me, are either dead or have disappeared. It is believed to this very day at Nirnier that the person stated as suffering from cholera died of poison, and nobody knows, or seems to care to know, how the cholera had been introduced.

Notes on the Effects of Very Powerful Electric Currents.

Dr. G. F. De Schweinitz thus writes in the *Therapeutic Gazette*, January 15, 1885:

The following report is intended to briefly place upon record the history and symptoms of two men who were prostrated by excessive charges of electricity, received from the apparatus at present in vogue for electrical illumination by means of the arc-light. The first case occurred in a man, aged about twenty-four years, who was admitted to Prof. H. C. Wood's wards, in the University Hospital, shortly after the accident, which happened as follows: This workman was walking through one of the departments of a large car manufactory in this city, carrying over his right shoulder a long iron bar, which also rested lightly against the side of his head. The upper end of this implement became entangled in the wires connecting the dynamo with the carbons, thus placing the man within the circuit, when, to use the expression of his comrades who witnessed the result, he was felled to the ground "as if struck by lightning." His fellow-workmen hurried to his assistance, found him entirely unconscious, and, having conveyed him to a neighboring room, sent a request for his admission to the hospital. When the reporter of these notes arrived, about a half an hour after the accident, he found the patient perfectly insensible and oblivious to all external impressions, face and skin surface natural, pupil normal and sensitive, pulse full, and rather slow, respirations somewhat labored, rather deep and the rate below normal, being ten or twelve per minute. The coma, pulse, respiration, were not unlike the beginning of the second stage of opium narcosis. No attempt at restoration was immediately made, but he was conveyed to the hospital and taken in charge by Dr. W. W. Jaggard, the then medical interne of that institution. After being sharply shaken and shouted at a few times, he slowly opened his eyes, his face assumed a bewildered expression, and he answered questions in a dazed sort of a manner. His temperature was normal, his pulse, perhaps, a little more rapid; his respiration, when he remained quiet, was slow. He complained of no pain, but only of a certain amount of disability in the motions of the right arm and leg. After drinking a cup of milk he fell into a quiet sleep, from which he did not awake until the following morning, the time being then a little after midnight. In the morning no evil effects from his accident were noted, except some muscular disability of the right side. He asked for his discharge, which was granted, and he passed from observation.

The second case also came under the notice of the reporter, and occurred during August of this summer in the large Bessemer works in a neighboring town. This mill is illuminated with Weston's duplex lamp, the dynamos being of the same make, five dynamos to fifty lights. A description of the accident cannot, perhaps, be more accurately given than in the words of the gentleman who experienced it:

"On a wet, rainy night, in an open shed, I received a slight shock when using one hand, protected by a cotton handkerchief, in adjusting the lamp. I received the final shock in trying to remove the lower carbon, using both hands again, supposed to be insulated by a double wrapping of cotton handkerchief, the one hand holding the carbon, and the other slacking off the adjusting set-screw. Now for my sensations: It seemed to me as if there was an instantaneous bright flash, which may have been due to the sudden change from light to so absolute a darkness that it appeared to have body. The next sensation, after ap-

preciating this inky darkness, was that of trying to tear myself away from something that held a terrible grip upon me. My hands seemed to hold on while my body was trying to get away, every nerve and muscle being strained to its utmost. My next impression was, when I opened my eyes and found I was lying upon my back, perfectly straight, but in exactly the opposite position to the one assumed when I was standing, showing that I had been completely turned around. One carbon was found about ten feet away from my one side, and the socket which holds the lower carbon about the same distance away from my other side. This I had torn out of the lamp. Above me the lamp was swinging violently. The whole time from the moment the current struck me until I picked myself up was less than three minutes."

When seen, this gentleman complained of no evil after-effects, except a great feeling of muscular soreness, produced, no doubt, in part by the number of bruises and brush burns which covered his thigh and back, showing how violently he had been thrown upon the ground.

The Treatment of Phthisis.

Dr. F. P. Atkinson thus writes in the *Edinburgh Medical Journal*, February, 1885:

No one, I think, can question the fact, that the treatment of phthisis has undergone a marked change for the better during the last twenty or thirty years. The cause of the disease is now more considered than the symptoms—specific treatment is abandoned—and residence is recommended in those climates which are most likely to increase the appetite, improve the character of the blood, and promote a healthy interchange of tissue.

Even during the continuance of winter, so long as the wind is in the south or west, gentle out-of-door exercise is preferred to confinement in-doors, and in many cases the dry, cold, bracing air of the Engadine to the warm, relaxing air of the Riviera. There can be no doubt that it would be a great advantage were all persons suffering from phthisis able to be treated in the climates most suitable to their particular case; but this, from various causes, is impossible, and we have to see what means we have at command for bringing about that improvement in health which is necessary in order to effect a cure.

First, then, I would say, it appears to me of little or no consequence what form of phthisis we are called upon to treat, and that the following remedies will be found suitable, with slight alteration, to all stages of the disease. Give syrup of the lacto-phosphate of lime and iron 1 drachm (concent.); tincture of nux vomica 5 minims; tincture of calumba 15 or 20 minims, with a little essence of lemon and water to the ounce, three times a day. A teaspoonful of pancreatic emulsion carefully mixed with water, or a teaspoonful of Lœflund's condensed cream emulsion, or half a pint of koumiss once or twice a day. If the appetite is bad to start with, keep the patient well supported wth Brand's essence of beef, or, better still, Valentine's meat juice, and milk; and if stimulant is necessary, give half a sherry glassful of St. Raphael wine twice a day. Paint the chest morning and evening with tincture of iodine till sore, then omit for a time, and afterwards commence the painting again. If there is much sweating at night, inject a hundredth part of a grain of atropia subcutaneously, or, especially if the cough is very troublesome, give 10 grains of Dover's powder at bedtime. In the commencement of an acute attack, or when any outburst of pyrexia occurs, it may be necessary to give large doses of quinine and digitalis (as much, for instance, as two grains of the former, and 5 or 7 minims of the tincture every two hours) in order to bring down the temperature; but still it must be remembered that treatment to be successful must be directed towards a general increase of nutrition. This holds good whether phthisis be proved to be due to germs or not. If there is much hæmoptysis, give either some hazeline or acetate of lead and opium. When vomiting has been a very urgent symptom, I have now and then found Dr. Hughes Bennett's treatment of great service, viz., 10 minims of medicinal naphtha, 1 drachm of the compound tincture of cardamoms and camphor mixture to the ounce, to be taken every four hours.

In most cases I have been able to get on very well without inhalations, but have no doubt they might here and there—such as, for instance, where there are very large cavities—prove of very great service. It is astonishing how many really bad cases improve under the above method of treatment; but it is, unfortunately, not altogether suited to the poor on account of the expense which it involves; yet even they, with continued use of the lacto-phosphates, not unfrequently undergo very material improvement. I consider the lacto-phosphates in every way preferable to the hypophosphites, and there can be no doubt we are deeply indebted to Dr. Dusart for such useful and extremely pleasant remedies. As he says, "they act as excitants of all the nutritive functions, ensure digestion, bring back or increase the appetite, and generally improve the vital energies."

A Case of Gastric Ulcer.

Dr. Osman B. Campbell reports the following case in the *College and Clinical Record*, January 1, 1885:

"I was called, on March 15, 1884, to see Miss R., aged twenty-two, who was suffering with gastric pain; she had had two attacks of hæmatemesis, and was considerably prostrated, from pain and inability to digest a sufficient quantity of food. I found that her trouble dated back four months, when she had had an attack of intermittent fever. Quinia and calomel were given, which broke up the fever, but she did not regain her health. She complained of a feeling of weight and soreness in the right side, near the region of the liver; her abdomen enlarged considerably, so that her clothes had to be widened to the extent of three or four inches; she was constipated, and had throbbing sensations about the umbilicus. She was jaundiced, and had frequent attacks of vomiting, when the contents of the stomach would be ejected, followed by bile. These conditions continued about two months and a half, when, upon vomiting, some black, partially digested blood was ejected. She noticed the same

day that her stools were black and tarry. From that time the taking of food would cause gastralgia and vomiting about twenty minutes after eating.

"Six weeks later, she came under my observation. I found considerable enlargement of the liver and spleen, some bloating of the abdomen, gastralgia and vomiting, excited by taking food. She had just vomited some blood, which I found to be partially digested. She complained of a fixed pain immediately under the ensiform appendix, extending through to the spine. I diagnosticated the case as a gastric ulcer, a result of portal congestion. I restricted her diet to skim milk, diluted with one-fourth lime-water, from three to four ounces to be given every three hours, and gave a purge of calomel, to relieve the portal circulation. I prescribed five-drop doses of liquor potassii arsenitis, three times a day, and gave twenty grains of quinia during the twenty-four hours.

"My patient began to improve immediately; there was no more gastralgia nor vomiting; nor was there any appearance of blood in the stools. Six months after I began treating the case all signs of the disease had vanished. The cause of the ulcer was, I believe, portal congestion, caused by malaria."

Note on Complete Aspiration.

Dr. David Christie thus writes in the *Med. Press*, January 28, 1885:

For some years past there has been much written regarding the use of the aspirator in cases of pleuritic effusion, and the talent displayed on this subject is creditable to the medical profession; but in using the aspirator, there has been one thing omitted that mars or nearly destroys its utility. I have waited more than two years for some one to find it out, but, strange to say, in vain.

The thing is as simple as making an egg stand on its end *when you know it*, and the only mystery about it is that no one seems to have thought of it. I have tried the partial aspiration as it is usually performed, and find that the pleural cavity refills in a short time; after complete aspiration it does not. The way it is managed is very safe and simple. I put a broad bandage round the chest that can be laced behind like a corset; then, as I pump the fluid *out*, I press the ribs *in* by tightening the bandage. I think when I do so it is unnecessary for me to explain that I prevent any internal organ from being displaced (at the same time keeping them at a proper pressure), and the ribs by their elasticity from acting as a suction-pump to cause a re-accumulation of fluid. I allow the bandage to remain on for some days. Any one who understands the action of a pump and a siphon requires no further explanation. Many imagine they do, but are mistaken; these I would advise to consult "Ganot's Physics." After a certain amount of fluid has escaped, dragging pains set in. Tightening the bandage instantly gives relief. Alternate aspirating and lacing should be continued until all is removed; then there is likely to be a fit of spasmodic coughing; the patient may spit some frothy mucus tinged with blood, but all such symptoms pass off in a few minutes, and do not return—at least that has been my experience.

I may add that the needle should be put in at such an angle that, after piercing the costal pleura, the point can be made to touch it again, so that when the pleuræ approach each other the lung may not be wounded; and when necessary, the pleural cavity should be made antiseptically clean.

The Management of Patients During Etherization.

Dr. H. L. Burrell thus concludes a paper on this subject in the *Boston Med. and Surg. Jour.*, January 29, 1885:

1. Before etherization, the surgeon should satisfy himself regarding the presence or absence of heart disease.

2. The safety of the patient and the comfort of the etherizer largely depend on the use of pure anhydrous sulphuric ether.

3. The best medium for the administration is one in which the ether can be given in a condensed form or largely mixed with air.

4. As a rule, the patient should have a brief, clear description of the sensations he is about to experience.

5. A room free from bustle and confusion before and after an operative procedure is an essential for quiet etherization.

6. Ether should be administered on an empty stomach.

7. The knowledge of the effect of a glass of wine upon a patient is frequently an indication of the exciting or stupefying effect that ether may have.

8. No mechanical impediment should exist to respiration.

9. The pulse and respiration are the safeguards of etherization.

10. The less ether used in an operative proceedure, the better the recovery of the patient from the immediate effects of the operation.

11. A little ether in children goes a long way.

Remaining, we have a number of questions on which, possibly, there is difference of opinion. The following suggest themselves to my mind:

The comparative value of the different brands of ether?

Whether it is better to pull the tongue forward or to push the jaw forward?

Whether any patient exists that cannot be etherized?

The comparative values of a sponge, towels, and inhalers?

The use of opiates and stimulants as adjuncts to etherization.

—The *Medical Herald*, January, 1885, tells us that the prize of 40,000 francs offered by the French Academy for some certain test of death, to prevent people from being buried alive, was given to a physician who announced that on holding the hand of the supposed dead person to a strong light, if living a scarlet tinge is seen where the fingers touch, showing a continuous circulation of the blood, no scarlet being seen if dead.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. Harrison Allen, of this city, in a reprint before us, describes a new method of recording the motions of the soft palate, especially with reference to the medical uses to which the method can be applied. The plan he describes is both ingenious and successful, and as he suggests may prove to have applications in other branches of science besides medicine.

——In a valuable paper on our table Dr. C. H. Hughes, of St. Louis, discourses wisely of such important topics as the Hygiene of the Nervous System and Mind; The Relation of the Nervous System to Cholera and its Prophylaxis and Neurotherapy; The Cure and Prevention of Dyspepsia as a Nervous Disease; The Neuropathic Diathesis—its Quarantine and Treatment.

——The *Transactions* of the American Dermatological Association at its eighth annual meeting makes a neat pamphlet of 26 pages. Abstracts of the papers read are given and a number of typical cases are described. The report is prepared by Dr. W. T. Alexander, of New York city.

——Dr. John V. Shoemaker's researches on the oleates in the treatment of skin diseases have been translated into German by the *Monatshefte für Praktische Dermatologie.*

——Under the title "One Hundred Years of Publishing," the house of Lea Brothers & Co. rehearse in a well-printed pamphlet the history of their firm and its antecedents since it was started in the year 1785. There are few firms in America who can point to such a record.

——A valuable report on the diseases of the ear in locomotive and other engineers, firemen and conductors, which may endanger the lives of the public, appears in pamphlet form from the proceedings of the American Medical Association, by Dr. Laurence Turnbull. It is an original study, and contains many interesting statistics.

——Dr. P. B. Porter will hereafter edit *Gaillard's Medical Journal*, and will have for collaborators Drs. T. Gaillard Thomas and George T. Harrison, of New York; Hunter McGuire, of Richmond, Va.; and C. H. Mastin, of Mobile.

BOOK NOTICES.

A System of Practical Medicine. By American Authors. Edited by William Pepper, M. D., LL. D., etc., assisted by Louis Starr, M. D. Vol. I., Pathology and General Diseases. 8vo., pp. 1094. Lea Brothers & Co., Philadelphia, 1885.

There are certain elements of novelty about the extensive undertaking which is commenced with this volume which cannot fail to recommend it to to the medical public. It is intended to be a study of the diseases which occur in American life, from the experience of American practitioners and teachers exclusively. This experience is to be obtained, not by culling here and there from the publications of the American profession, but by a series of monographs prepared by the most eminent American physicians on topics of their own choosing, and hence those in which they are most interested. Certainly no other plan could be suggested by which the reader could be secured a higher order of literary and scientific merit. In this design, we should add, the word "American" means Canada and the United States.

This first volume of the work is occupied with pathology and general diseases. The introductory essays are on General Morbid Processes, by Dr. R. H. Fitz; General Etiology and Diagnosis, Dr. Henry Hartshorne; Hygiene, by Dr. John S. Billings; and Drainage and Sewerage in their Hygienic Relations, by Mr. George E. Waring.

Following these articles of a general nature, the maladies are described which in the nosology of the Royal College of Physicians are classed as "General Diseases," such as typhoid and typhus fevers, variola, rubeola, diphtheria, cholera, pertussis, influenza, etc. The principal writers in this department are Drs. J. H. Hutchinson, James N. Hyde, W. A. Hardaway, Alfred Stillé, John M. Keating, James Law, A. Jacobi, J. Lewis Smith, etc. In all, there are twenty-one contributors to the volume, thus presenting a wide range of observation from a most competent body of observers. The result is a series of monographs representing the very best efforts of American medicine.

The scope of the work is intended to be extensive. It will embrace hygiene, gynecology, the diseases of the male sexual organs, diseases of the rectum, etc., which are frequently omitted or else inadequately treated in many works on practice.

The book is handsomely printed in clear type, with a sufficient number of illustrations.

—Mrs. Philander Peck, of Chicago, has recently left a legacy of $400,000 for the erection and support of a Home for Incurables in that city.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address
DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

THE INCREASING ADULTERATION OF MEDICINES.

The increased adulteration of drugs has lately attracted the earnest attention of health boards. Such adulteration is greatly facilitated by the custom now so widely established, of dispensing medicines already combined in various forms by wholesale drug manufacturing houses. Pills, elixirs, troches, suppositories, tablets, wafers, and we know not how many forms, are no longer put up by the retail druggist, but are manufactured in quantities at large establishments, and the retailer merely aids in distributing them.

Hence, an important check on the fidelity with which the drug is compounded is removed to a distance from the physician. If the remedy does not answer his expectations, he cannot visit the drug store and verify the accuracy with which his prescription was prepared.

What is his remedy?

He cannot himself make analyses of these preparations. Such analyses are delicate, time-consuming, and difficult.

His only remedy appears to be in insisting on the preparations of trustworthy houses, of high repute, who by energy, skill and honesty have gained a reputation which it will not pay them to risk by placing on the market merchandise inferior in quality or diminished in quantity.

How is he to learn of such houses?

Perhaps the advertising pages of the highest class medical journals will offer the readiest means. As a rule, manufacturing druggists who do not advertise in these channels are either weak financially, and hence have a strong temptation to adulterate their goods; or their goods are of such questionable character that they seek to avoid publicity and checks of medical journalism, and introduce them by distributing private circulars, in which any statement can be made and not questioned, or else by traveling drummers, who are equally uncontrolled in their statements.

In fact, the physician may be pretty sure that the firms whose advertisements do not appear in any of the five or six principal medical journals, are absent for good reasons; and it would be as

well for him to discredit the statements of all houses who profess to prefer other means of reaching the profession—they do so for reasons which, as a general thing, they would not be willing to acknowledge.

Notes and Comments.

Twenty-five Cases of Abdominal Section.

Dr. J. Greig Smith reports the following cases in the *Lancet*, Jan'y 19, 1885. They are as follows: Ovarian cystoma, 17; solid growths of ovaries, 2; pyosalpinx, 2; hæmosalpinx, 1; exploratory, 3. A prolapsed, adherent, and diseased ovary successfully removed through the vagina is not included.

Among cases of cystic disease is included one where the tumor was mixed dermoid and cystic. In three cases the second ovaries were large enough to be reckoned as separate tumors; in five more the second ovary was removed because of incipient disease.

Of the cases of solid growth, one was a pure fibroma of the ovary, measuring seven by eight inches in its diameters; in the other not only were both ovaries changed into solid growths, each about a pound in weight, but both Fallopian tubes were distended with a fluid fatty material, crowded with crystals of cholesterine.

One of the cases of pyosalpinx was the worst of the series. The patient had been very ill for two months; and when seen was in a low typhoid condition, with high evening temperature (103°) and rapid pulse (120). She had also chronic bronchitis, with constant cough, and some fluid in the right pleura. The tumor was very thick-walled, rotten, almost gangrenous in parts, and, it need scarcely be added, adherent all over, more particularly to the bladder, uterus, and rectum. It contained about eight pints of highly offensive pus. There was free bleeding from innumerable points, which was checked by pressure of sponges. Part of the cyst wall, firmly adherent over the iliac vessels, was surrounded with a ligature and left behind. The operation had to be hurriedly concluded (within the hour), as the patient was near dying on the table. The treatment adopted was the following: Nutrient peptonized enemata, drainage, and daily syringing of the abdomen so long as the discharges continued putrid. The ligatured portion came away through the wound as a slough, large enough to fill a three-ounce bottle. The patient recovered and went home, but now, eight months since the operation, there exists a sinus in the abdominal parietes, which is gradually closing.

Of the exploratory operations in one case the tumor was found to be malignant, and to have invaded the peritoneum; the patient went home after a month, and lived for nearly a year. A second was found to be encysted peritonitis from miliary tuberculosis. She recovered well from the operation, and died in nine months of her disease. The third was found, as was suspected, to be one of movable kidney, which was fixed.

Of these cases all recovered save one, and here the cause of death was volvulus. The patient was a broken-down woman of fifty-three, a cripple, with her joints all distorted from chronic rheumatic arthritis. The operation was not peculiarly difficult, and she appeared to be out of danger, when, on the fifth day, violent vomiting set in, which became stercoraceous in the end, and killed her in twenty-four hours. At the post-mortem examination a kink in the bowel, which was very dark and congested for a foot of its length above it, explained what, perhaps, ought to have been diagnosed during life. The rapidity with which she succumbed was easily explained by her general feebleness.

In all these cases Listerism was observed in its fullest details, even to catgut (with two or three exceptions) for the pedicle.

The operations are done in the general operating theatre, and no restriction whatever is put on students or visitors who may care to be present. For a week or ten days after operation the patient is kept isolated in a small ward; thereafter she is returned to the general ward. He adds that the infirmary building is a century old, that it stands in a low-lying, poor neighborhood, and that its wards, affording less than eight hundred cubic feet to each patient, are always full, often overcrowded.

Hydrocele in the Female.

Hennig, of Leipsic, read a paper on this subject before the Society of German Naturalists and Physicians, in Magdeburg.

Hydrocele in the female, he said, was very rare; he has been able to find only thirty-nine cases recorded in literature, and had two cases in his own practice. Apart from their interest to the gynecologist, these cases merit the attention of accoucheurs, as hydrocele may render delivery very difficult, or even impossible; furthermore, the exudation, by passing up the inguinal canal

into the abdomen, during labor, may cause peritonitis; three instances of this accident are recorded. It may also cause sterility; a case is reported in which sterility of fourteen years' standing was cured by removal of the hydrocele. Zuckerkandl made post-mortem examinations of the bodies of nineteen young girls, the ages ranging from one to twelve years; in four cases he found the so-called Nuck's diverticulum, bilateral in three cases. If the hydrocele communicates with the abdominal cavity, the contents may be forced out into the cavity. In many cases small sacs are found in the course of the round ligaments; they are liable to occur after traumatism, and to become inflamed.

Hydrocele occurs from the seventh to the seventieth year, and is more frequent in women who have borne children than in nulliparæ. In 8 cases it was on the right side, in 6 on the left, in 2 it was bilateral. Of 40 cases, the hydrocele completely filled the canal in 25; of these, 3 did not communicate with the abdominal cavity, and 15 were closed cysts. In 5 cases the fluid was bloody.

The affection begins painlessly. At first the swelling is slight, and disappears on lying down. Though there is seldom any fever at first, it comes on when the hydrocele becomes inflamed, which may occur from excessive tension. Erysipelas has also been observed before an operation. Hydrocele in the female has been mistaken for hernia; the diagnosis can be easily made in some cases by the use of the aspirator needle. The hydrocele has been known to suppurate in a few cases, but the suppuration has never extended to the abdomen. Of 28 cases of hydrocele, 23 were cured, and the hydrocele returned in 5 cases. The treatment consists at first in placing a bandage over the sac, and later in making an incision and filling the sac with charpie.—*Centralbl. für Gynäk.*, October 11, 1884.

The Hereditary Transmission of Pulmonary Consumption.

This is a most interesting question, and one about which there is much less unanimity of opinion than we found some years since. Dr. John L. Davis publishes a paper on the subject in the *Cinn. Lan. and Clinic*, January 24, 1885, based upon an analysis of one thousand cases in which reliable family histories were given. He thus concludes:

In concluding the subject of the family predisposition to consumption it is proper to state that the results of the analyses of these one thousand cases lead me to differ decidedly from the opinion of Walshe (*Med. and Chir. Review*, vol. iii.): "Phthisis in the adult hospital population is, to a slight degree only, a disease demonstrably derived from the parents." And my results differ also from those of the directors of the Mutual Life of New York, who declare "The existence of an hereditary tendency to consumption has been generally asserted and believed, but has not been proved; our statistics afford the proof. They show that heredity only occurs in a minority of instances."

Finally, I will briefly relate the history of one family which has come under my personal observation; a record that illustrates a most remarkable hereditary transmission of consumption.

Mr. John T., of Ross county, Ohio, had by his first wife twelve children; the wife died of consumption, and Mr. T. married again and had eight children, and they are all living and neither they nor their descendants have as yet shown a single instance of consumption. But of the twelve children of the first wife, three died early and left no posterity. The remaining nine had children, but these all died of consumption before middle age, except the children of two of the nine. Of these two children of John T., one, a daughter, died of consumption after having had twelve children; of these (third generation), four died as infants; three adults have died of consumption, and three more are now suffering with the disease.

The other survivor was the eldest son of John T., Henry by name. Henry T.'s first wife was phthisical; she had eight children, but they all and she died of consumption.

The second wife also was consumptive; of her nine children, eight, with their mother, died of this disease.

A third wife of Henry T. had five children, but they all died in early manhood of consumption, and their mother soon followed them.

Henry T. married a fourth time, but died soon after of phthisis, leaving no children by his last wife.

This history, which is absolutely trustworthy, illustrates the remarkably hereditary character of pulmonary consumption.

The Uses of Sulphide of Calcium.

Before the West London Medico-Chirurgical Society (*Med. Press*, January 7, 1885), Mr. R. F. Benham read a paper on this subject, in which he remarked that in his opinion very many of the failures in the use of this drug were due to too sparing administration. Dr. Ringer drew the at-

tention of the profession to this drug in a paper in vol. i., *Lancet*, 1874, in which he stated that sulphide of calcium possessed the power of arresting and preventing suppuration in such cases as boils, carbuncles, scrofulous and glandular enlargements, and in many skin diseases. After reading many cases treated by various practitioners, the author remarked on the number of unsuccessful cases, and said the quantity given had been too small. A $\frac{1}{6}$-grain dose might cure in one case, but not necessarily in another. He regarded the appropriate dose for an adult to be one grain in pill "ter die," but if after, say a week, no improvement occurred, he made an increase of one grain per diem, or every few days, until about eight grains daily were reached. The dose which had hitherto been regarded as poisonous, he found did not produce alarming toxic symptoms; secondly, only a small quantity of the drug taken is decomposed in the alimentary canal to form H_2S; and last, but not least, from the ordinary dose he did not find anæmia produced, but on the contrary, even where six or eight grains daily were given, general improvement in health resulted even when the drug failed in curing the symptoms for which it had been administered. The author maintained that the physiological action of the drug is not due to its conversion into H_2S in the organism; it could not be that only a small portion is absorbed and the remainder passed off unchanged—for if so, why should a large dose effect a cure when a small one failed? The author preferred giving the drug in pill, as by this means the taste is unobserved. Mr. Benham read notes of a series of a large number of cases treated with success, and also recommended the drug in phthisis, typhoid, and small-pox.

The President, Mr. Frederick Laurance, had found the drug cause intestinal derangement; he had found it useful in gum-boil. Dr. James Thompson found one-tenth grain the safest dose to begin with. Mr. Maitland Thompson had not found it useful in strumous glandular affections.

The Power of Imagination.

Before reporting the following case which Dr. George C. Kingsbury records in the *Brit. Med. Jour.*, Feb'y 7, 1885, let us say that it looks very much like another illustration of the "*Power of Imagination.*" He says: "A few days ago, I was called in to see a female patient, aged 32, who was suffering great pain from an ulcer over the right tibia. The ulcer communicated with some superficial necrosis of the bone, but the patient had refused the surgical aid of several other practitioners, and now rejected mine also. In order to give her temporary relief, I ordered her to take half a grain of codeia, and to have a linseed-meal poultice applied over the ulcer. She strongly objected to the poultice, saying that, for the last four years, she had had an attack of asthma each time a linseed-poultice had been used. Not crediting this, I insisted on the poultice being put on. Three hours later, I was summoned to see her, as her sister thought she was dying. I found her livid and struggling for breath, and certainly in as bad an attack of asthma as I ever saw. The offending poultice was removed, and the attack gradually subsided. This patient is not troubled by any other kind of poultice; in fact, she is really fond of oatmeal in this form. I have tried whether the dust of dry linseed-meal would induce an attack, but with negative results. If, however, a linseed-poultice be made near her, even though not for her use, she is at once threatened by a feeling of constriction of her chest. Another curious sequence in this case was the appearance of urticaria on the back, chest, and arms, and of a crop of herpes where the poultice had been.

"As exciting causes of asthma, the dust of ipecacuanha, flax, scammony, oats, have all been known. Trousseau relates the case of a chemist who could not powder linseed without having a fit of asthma. In this case, however, the dust had no injurious effect; and I fancy the asthma was produced by the smell given off with the steam of the poultice."

Round-Celled Sarcoma.

Dr. A. C. Lamothe Ramsay thus writes in the *Northwestern Lancet*, February 15, 1885:

Round-celled sarcoma is a much rarer affection than is generally supposed; its favorite seat is the periosteum of the bones and the connective tissue, and it is very seldom observed in the integument, which is the favorite location of epithelioma. The diagnosis is only confirmed by a thorough microscopic examination of a hardened section stained with carmine. To the naked eye the tumor has the appearance of a soft, whitish, non-vascular growth, of longer duration than epithelioma, less vascular, less painful, less malignant; for it is propagated only by extension into the neighboring tissues, and not by metastasis, as epithelioma. The sarcoma tends to grow—it is a hyperplasia; the epithelioma tends to destroy, producing necrosis by pressure of the stroma on the surrounding connective tissues.

The epithelioma also spreads in the parenchyma

by projection of the epithelium through the blood and lymph-vessels; the round-celled sarcomas have their vessels intact, even enlarged.

My case was in a heretofore healthy Pole, aged forty, who for the last three years has had growth on his right thumb, which increased slowly and steadily. When I saw him it was larger than a silver dollar and almost encircled the thumb, being situated over the phalangeal articulation, and having a slightly red and indurated base.

It is useless to add that the only treatment was amputation, which was performed at the carpo-metacarpal articulation. As to the question of recurrence after extirpation, I think it less liable to recur than the simple epithelioma, both because the lymphatic glands are very rarely affected in round-celled sarcoma, and on account of the absence of spindle-shaped cells.

Xanthelasma.

Of this unusual affection, Dr. W. S. Thorne thus writes in the *Pacific Med. and Surg. Jour.*, February, 1885:

This somewhat rare affection of the skin, was first described by Monsieur Rayer, of Paris, under the name of *Plaques Jaunatres des paupières*. William, and after him, Addison and Gull, describe this affection under the nomenclature of Vitiligo. Most writers ascribe it to an apparent relationship to some liver affection, or to diabetes. In four autopsies of xanthoinic patients reported by Murchison, Moxon, Fogge and Pye Smith, hepatic disease was found in all. I have recently had the opportunity of observing for two years or more a patient suffering with this unpleasant deformity, in whom no trace of hepatic or any other disease is manifest. The patient, a female, is 38 years of age. The spots began upon both superior lids seven years ago simultaneously, as small yellow maculæ. They now involve nearly the entire surface of the lids. There are a few detached patches upon the lower lids, and at the outer canthus of each eye. The spots are elevated, slightly tuberculated, and in color that of a clean, new chamois skin (Naples Yellow). There is no unusual sensation in them, save an occasional itching; their area is slowly increasing. The minute anatomy of this morbid growth reveals hypertrophy of the connective tissue with localized fatty deposits. The connective tissue corpuscles are greatly increased and are of a yellow color. As my patient is extremely fair and the skin otherwise free from maculæ of any kind, it would seem that the affection of the lids is fairly attributable to perverted local nutrition, and not to hepatic derangement. It is, perhaps, due to that peculiar habit of body wherein the method of *forming* and *nourishing* tissues is faulty, the only visible evidence in this patient of *struma*.

Cocaine in Minor Surgery.

Dr. Irving D. Wiltnut contributes to the literature of this drug by writing as follows in the *Northwestern Lancet*, February 15, 1885:

I proposed to extirpate a fatty tumor the size of a hen's egg, situated near the ankle-joint, a little above the outer malleolus. My patient consented to the use of cocaine. I accordingly injected fifteen drops of a four per cent. solution into the body of the tumor. After waiting fifty seconds, I made my incision over the tumor, from above downward. I then separated, with some difficulty, the skin and cellular tissue from the organized mass, and, in my attempt to sever its connection with the tissues, I was obliged to use the knife quite freely. There was little bleeding —soon controlled by the free use of cold water. The several parts were properly adjusted, stitched; a compress and a roller bandage completed the operation and dressing.

During the whole of this operation my patient looked on, an interested spectator, but confessed no pain. The incision with the knife, as well as the force required to separate the tissues from the tumor, and the final force required to separate the mass from the living tissues, did not cause pain—no, not even a sensation.

The usual sick stomach followed the operation, but this cannot be ascribed to the use of cocaine.

My patient was a man of intelligence and of unquestionable integrity, so that, as regards the total absence of pain, I do not regard I have been deceived any.

A Treatment of Acute Dysentery.

Dr. Wm. J. Parker thus writes in the *Mississippi Valley Medical Monthly*, November 10, 1884:

For dysentery proper—there being no manifestation of the typhoid condition, and the bright red blood in the alvine dejections not profuse—the following is my plan of treatment for an adult:

℞. Oleum ricini, ℥i.
Hydrarg. sub-mur., gr. x. M.
Sig.—Every hour, until a "good free (dark) passage" is procured.

And ofttimes it requires five potions to do it. Moreover, if the *five* do not bring about the free passage, I discontinue the calomel and endeavor to evacuate the bowels at once by continuing the oil—large doses every hour. As soon as possible

after the bowels *are* evacuated, I commence with quinine. S.—Five grains every three or four hours until my patient is cinchonized. To control the tenesmus, tormina and *pains*, a half grain of opium, or better, four grains of Dover's powder might be added to the quinine; but, instead of giving an opiate in this manner, injections per anum of starch water and laudanum might produce a better effect. For the fever, if purely dysenteric, I give aconite. As a rule it is necessary to "carry out" this treatment every odd day, *for a time*. You may sigh; nevertheless this plan of treatment, however heroic the first part, acts most happily in *my* hands.

Absence of Vagina, Uterus, and Ovaries in an Apparently Well-Built Woman.

In the *New York Med. Jour.*, January 24, 1885, Dr. Henry J. Garrigues reports an abstract of this case. He publishes the case because it was usually said that there should be some signs pointing to such a condition in the appearance of the patient; especially that there should be a weakly, imperfect general development, absence of the mammæ, etc., but in this case there were absolutely no such signs. Even on examining the external genital organs one would have supposed the patient to be quite normally developed; it was only on searching for the vagina that he discovered the condition described.

The case was also interesting as showing the manner of natural development of the vagina and uterus. One point which had puzzled him a little was the history of the monthly molimen, for he had been unable to find any trace of ovaries. The patient, however, had some headache and general malaise almost constantly, and we could easily imagine that these symptoms might be increased a little every month.

The question might arise whether he was warranted in telling the patient that nothing could be done for her. Of course, if a uterus had been found, the treatment would have been to make an artificial vagina; but would it be proper to make an artificial vagina for the sole purpose of coition? He thought not; the woman would be exposed to much danger thereby. The operation itself would be dangerous, and the act of copulation in this artificial canal would expose her to constant danger.

Cocaine in Rectal Surgery.

The *Lancet*, January 17, 1885, says that cocaine seems destined to play an important part in the treatment of painful affections of the rectum and genito-urinary system. Dr. Bettelheim, of Vienna, reports the case of a man, aged seventy-four, who had well-marked anginal attacks, the result of atheroma of the aorta and ossification of the coronary arteries. For some time he had, in addition, complained of rectal and vesical tenesmus. Percussion over the bladder showed that it was not dilated, and rectal examination demonstrated the fact that the prostate was much enlarged and probably the cause of the trouble. Cacao butter suppositories were ordered, each containing half a grain of muriate of cocaine. One of these was introduced into the rectum at bedtime, and the patient slept well, and was not troubled during the night. The beneficial effects were apparent the whole of the following day. The suppository was not given that evening, and the patient passed an uncomfortable, restless night. The next day another suppository was ordered, and acted as well as the first. From the promptness and efficacy of the cocaine in this case, a brilliant future may be anticipated for the alkaloid in this department of surgery. It is now being largely used in many of the London hospitals in the treatment of piles, fissure, and fistula.

Vinegar in Diarrhœa and Dysentery.

Premising that Dr. John H. Brinton used to recommend, fifteen years ago, injections of cider vinegar in gleet, we note the following practical contribution from Dr. Amos Sawyer to the *St. Louis Med. and Surg. Jour.*, January, 1885:

"About a quarter of a century ago, when giving me some good advice for a young practitioner to follow, the late Dr. B. F. Edwards, of St. Louis, Mo., whose accuracy in the measurement of the action of remedies, truth in statement, and justice toward the members of the profession, made him a shining light in the early history of our State, among other things, said: 'Never make fun of an old woman's remedy, for not only will you give offense and thereby injure your practice to the extent of her influence, but you may throw away what would have proved upon trial to be a valuable adjunct in your practice.' He then cited this case to illustrate the importance of his injunction: 'In 1830, while practicing in Madison county, Ill. I was induced by the representations of *an old woman* to make the trial, in dysentery and diarrhœa, of tablespoonful-doses of *pure cider vinegar*, with the addition of sufficient salt to be noticeable, and it acted so charmingly that I have never used anything else.' He was prescribing it in 1870, making a period of forty years."

Cocaine in Vaginismus.

In the *Medical Press* we read that Dr. G. De G. Griffith has found this new and greatly-vaunted remedy useful in the above condition. Speaking of a case of vaginismus and dysparæmia, he says:

"The patient came to me suffering very acutely; not only was pressure on the perineum exquisitely painful, but the bare touching it was pain; indeed, blowing on it produced distress, and so intolerable was the suffering that examination had to be completed under chloroform. On the third occasion of attending the patient, I mopped the perineum, fourchette, and lower part of the vagina with a solution of the cocaine, after which I was able to introduce the large-sized Fergusson's speculum, which was retained for about two hours, as steady, continuous pressure had been found to give relief. I wish particularly to draw attention to the ease procured by the cocaine, although it was transient."

Valoid of Coca.

The *Lancet*, January 3, 1885, tells us that the valoid is made from the fresh leaves of the coca plant, each drachm representing that weight of the crude drug, including the whole of the alkaloidal and other principles. It has been extensively employed of late, and, curiously enough, is found to exert a double physiological action. In small doses it acts as a sedative promoting sleep, whilst in larger quantities, such as three or four drachms, it stimulates the nervous system and induces an increased capacity for mental exertion. It has been used with much success in sleeplessness arising from overwork or worry and anxiety, and also in the treatment of impotence, spermatorrhœa, and a number of allied diseases. It has no toxic action.

Ointment for Syphilitic Ulcers.

The *Union Médicale* says that M. Terrillon prescribes the following: Pyrogallic acid and starch, of each twenty parts; vaseline, sixty parts. After mixing, the ointment is to be kept in a completely closed bottle, and is to be applied once a day to venereal ulcers, making two applications when the ulceration is very extensive. The sores lose their virulence after the first dressing. In place of the ointment a powder may be spread over the ulcer, by means of a small bellows, composed of equal parts of pyrogallic acid and starch.

—Dr. E. S. Gaillard, editor of *Gaillard's Medical Journal*, died in New York, February 2.

Correspondence.

On Muriate of Cocaine.

Eds. Med. and Surg. Reporter:—

So much is being written in regard to the use of muriate of cocaine, that any observation tending to establish it on a reliable basis will, I believe, be welcome to the profession. As a local anæsthetic to mucous surfaces with a limited application, its value seems pretty well established. But that it will mitigate the pains of labor by painting over the os uteri, in which the whole organ shares in the work, as some enthusiasts have claimed, to me seems simply absurd; not to mention the waste of a valuable and expensive remedy, which, at present at least, demands of us an economized use.

My use of it is limited, with one exception, which I briefly append, to traumatic conjunctivitis, with the results heretofore reported.

About Christmas, a little 2 years old girl in one of my families, unknown to its parents, ate a quantity of dough, of which was being constructed one of those gastric abominations, Christmas chicken-pie. Beyond a slight febrile condition, no immediate symptoms were manifest. Soon after Christmas dinner, which consisted of a generous portion of the pie in question, vomiting occurred, continuing through the night at frequent intervals, followed toward morning by brisk purgation. At this juncture I was called, and deeming the digestive tract pretty well evacuated, gave small doses of Dover's powder, combined with minute doses of sub-chloride. In a few hours a brisk convulsion occurred. Castor oil was now administered, which soon revealed the offending substance to be dough, numerous large boli of which were passed at frequent intervals for twenty-four hours. By this time extensive irritation of the rectum was manifest by violent and long-continued tenesmus. Nervous exhaustion indicated by convulsive twitchings, rolling of the head from side to side, disturbed sleep, etc., rendered the case an anxious one. Injections of starch-water and laudanum were of no avail, as with one or two exceptions they could not be retained at all, being forced out beside the rectal tube. A 3 gr. solution of nitrate of silver was of little avail.

I conceived that the muriate of cocaine would be useful if it could be applied. I could not brush it over the surface, the ideal method; no means of injection, and at that time no data as to dose. In this dilemma, I resorted to my cast-away instruments, and found a silver tube some two inches in length, one-eighth inch in diameter, and tipped with a perforated bulb the size of a common pin. I plugged the open end of this, and through the plug thrust the needle of my hypodermic syringe, thus producing an ideal syringe for this purpose. I then drew into my syringe-barrel 15m of a 4 per cgnt. solution of cocaine, (P. D. & Co.,) and, first penciling the anus, injected, with little resistance from my little patient.

This small amount, about 10m, as I estimated the tube would contain about five, was not likely to be rejected. A refreshing sleep of some three

hours followed, the tenesmus did not return, and convalescence was soon established. I should not again hesitate to inject 20 or 30m in a future case, if so much seemed necessary to reach the point of irritation. In such cases as these, I doubt not the cocaine will find a wide field of usefulness, and meet a long-felt want.

L. J. Gibbs, M. D.

Chicopee Falls, Mass., February 10, 1885.

News and Miscellany.

How Long Are Scarlatinal Patients Infectious?

The *Med. Press*, January 21, 1885, says:

A dispute which is going on at the present time between the Manchester Health Committee and the Board of Management of the Royal Infirmary, illustrates the importance of this question, and the difficulty there is in giving an authoritative answer to it. The former allege that the latter, who are responsible for the management of the Monsal Fever Hospital, are retaining the cases of scarlet fever sent to them an unnecessary time, and they have, in consequence, refused to pay their accounts in full for the last two quarters, deducting some $2,600. To understand the relations between the two authorities, we may state that in 1881 Manchester obtained powers for the compulsory notification of infectious disease, and at once took steps to provide suitable hospital accommodation. Having no fever hospital belonging to the Corporation, arrangements were made with the Royal Infirmary, and Children's Hospital, at Pendlebury, to receive infectious cases from the city, the remuneration given being a fixed sum annually, and in addition, $3.50 to $5.00 per week per patient, according to the number sent. The sums paid during the last two or three years amounted to about $25,000 per annum to the Royal Infirmary, and $5,000 to the Children's Hospital. At the beginning of last year, some complaints were made by another authority, who sent patients to Monsal, that they were sending out scarlet fever patients who were still desquamating, and thereby spreading the disease. These complaints caused the Monsal authorities to keep their convalescents for a longer period, and it is to the enhanced expenditure incurred thereby that the authorities of the city of Manchester take exception. They allege that some cases have been retained as long as fourteen weeks, and the majority have been kept considerably over six weeks, a period which their medical adviser, the health officer for Manchester, considers ample. The Board of Management of the Infirmary have passed a resolution calling on the city authorities to pay the sum deducted, forthwith, at the same time refusing to receive more cases except on the understanding that their own medical officers are to be the sole judges of the fitness of the cases to be discharged. The further question then arises for consideration by the corporation, whether it shall establish an infectious hospital of its own, and thus be independent of the Monsal Fever Hospital?

The question in which we, as representing the rofession at large, are most interested, is as to the length of time it is necessary to retain scarlet fever patients in quarantine in order to render them absolutely free from the suspicion of spreading the disease on their discharge? We take it as certain that, as a whole, the profession are agreed that the process of desquamation which usually follows the rash must be complete before the patient is discharged, very few being found to agree with Mr. J. Makinson Fox, Medical Officer of Health for Midcheshire, who believes "that a fortnight after the cessation of the fever, the epithelium that was shed was, after disinfection of the skin, absolutely harmless." We believe this latter opinion to be not only radically wrong, but extremely dangerous, and to act upon it would seriously endanger the lives of our patients' friends.

We do not believe the disinfectant exists which would effectually destroy the germs or microbes of scarlet fever present in or beneath the epithelial layer without injuring or destroying the skin itself, and nothing short of a complete desquamation will render the patient free from infection. But then the difficulty arises, that while in the majority of cases the skin becomes smooth by the end of the fifth or sixth week, desquamation, especially about the feet or heel, continues for two, or even three months. Is it necessary to retain the patient for this period? We can hardly believe that it is. We believe that if during the period of the fever, or the three weeks during which time the patient usually keeps his bed, he is washed daily with carbolic soap, or water containing some sulphurous acid, and then has warm baths daily during the next three weeks, soaking his feet in water to peel away the thick skin that so pertinaciously adheres, he may be discharged with the greatest probability of safety at this period—the end of the sixth week—and with absolute safety by the end of the eighth. If desquamation reappears after his discharge, we should not think it of any consequence. If the present dispute should be the means of establishing convalescent homes for fever patients where the cost of maintenance would be far less than when in hospital, it will have served a useful purpose.

How the Commander of the "Monitor" was Wounded.

The fight between the "Monitor" and the "Merrimac" is the subject of *The Century* war series for March. From the late Commodore S. D. Greene's paper, entitled "In the Monitor Turret," we quote the following: "Soon after noon a shell from the enemy's gun, the muzzle not ten yards distant, struck the forward side of the pilot-house directly in the sight-hole, or slit, and exploded, cracking the second iron log and partly lifting the top, leaving an opening. Worden was standing immediately behind this spot, and received in his face the force of the blow, which partly stunned him, and, filling his eyes with powder, utterly blinded him. The injury was known only to those in the pilot-house and its immediate vicinity. The flood of light rushing through the top of the pilot-house, now partly open, caused Worden, blind as he was, to believe that the pilot-house was seriously injured, if not destroyed; he therefore gave orders to put the helm to starboard and

'sheer off.' Thus the 'Monitor' retired temporarily from the action, in order to ascertain the extent of the injuries she had received. At the same time Worden sent for me, and leaving Stimers the only officer in the turret, I went forward at once, and found him standing at the foot of the ladder leading to the pilot-house.

"He was a ghastly sight, with his eyes closed and the blood apparently rushing from every pore in the upper part of his face. He told me that he was seriously wounded, and directed me to take command. I assisted in leading him to a sofa in his cabin, where he was tenderly cared for by Dr. Logue, and then I assumed command. Blind and suffering as he was, Worden's fortitude never forsook him; he frequently asked from his bed of pain of the progress of affairs, and when told that the 'Minnesota' was saved, he said, 'Then I can die happy.'

"When I reached my station in the pilot-house, I found that the iron log was fractured and the top partly open; but the steering-gear was still intact, and the pilot-house was not totally destroyed, as had been feared. In the confusion of the moment resulting from so serious an injury to the commanding officer, the 'Monitor' had been moving without direction. Exactly how much time elapsed from the moment that Worden was wounded until I had reached the pilot-house and completed the examination of the injury at that point, and determined what course to pursue in the damaged condition of the vessel, it is impossible to state; but it could hardly have exceeded twenty minutes at the utmost. During this time the 'Merrimac,' which was leaking badly, had started in the direction of the Elizabeth river; and, on taking my station in the pilot-house and turning the vessel's head in the direction of the 'Merrimac,' I saw that she was already in retreat. A few shots were fired at the retiring vessel, and she continued on to Norfolk."

Khartoum.

"The Land of the False Prophet," is the title of the opening illustrated article in the March *Century*, by General R. E. Colston, who was formerly a bey in the Egyptian service. From it we quote the following; "Khartoum is a city numbering between fifty and sixty thousand people. Several European consuls reside there. The American Consul was Azar Abd-el-Melek, a Christian Copt from Esneh, and one of the principal merchants. The European colony is small, and continually changing; for Khartoum is a perfect grave-yard for Europeans, and in the rainy season for natives also, the mortality then averaging from thirty to forty per day, which implies three thousand to four thousand for the season. Khartoum is the commercial centre of the Soudan trade, amounting altogether to sixty-five million dollars a year, and carried on by one thousand European and three thousand Egyptian commercial houses. Drafts and bills of exchange upon Khartoum are as good as gold in Cairo and Alexandria, and *vice versa*. From official sources I learned that the city contained three thousand and sixty houses, many of them two-storied, each of them having from ten to one hundred and fifty occupants. Stone and lime are found in abundance, and the buildings are, after a fashion, substantial, the houses belonging to rich merchants being very spacious and comfortable. There are large bazaars, in which is found a much greater variety of European and Asiatic goods than would be expected in such distant regions. In the spacious market-place a brisk trade is carried on in cattle, horses, camels, asses, and sheep, as well as grain, fruit, and other agricultural produce. Many years ago an Austrian Roman Catholic mission was established and liberally supported by the Emperor of Austria, and by contributions from the entire Catholic world. It occupies a large parallelogram, surrounded by a solid wall. Within this inclosure in beautiful gardens of palm, fig, pomegranate, orange, and banana trees, stands a massive cathedral, a hospital, and other substantial buildings. Before the people of Egypt and the Soudan had been irritated by foreign interference, such was their perfect toleration and good temper that the priests and nuns, in their distinctive costumes, were always safe from molestation, not only at Khartoum, but even at El Obeid and the neighborhood, where the majority are Mussulmans and the rest heathens. It was stated some months ago that Gordon had abandoned the Governor's palace, and transformed the Catholic mission into a fortress, its surrounding wall and massive buildings rendering it capable of strong resistance."

A New View of Cholera.

The Italian correspondent of the *Chicago Medical Journal* (January, 1885), gives the following amusing extract from a pamphlet on cholera, written by Leonard L.:

"Having thus spoken, Leonard asks himself: 'What is cholera?' Upon this question is what he has been meditating in his solitude in the country since 1854. At last he has it. '*It is nothing more than a consequence of the displacement of the worms of which we are made up.* A sudden fear, an indigestion, or any other disorder which shakes, but does not kill the delicate mass of worms, will arouse them, and they, leaving their normal place, will assail and suffocate the patient, as frequently happens in nursing children. The rice-pap discharges are nothing else but a mass of smaller worms with their excreta, triturated by the current of the larger worms which assail the belly, stomach, and throat. The greater or less intensity of the assault are proportionate to the greater or less intensity of the disease, and hence the *cholerine*, the *cholera*, and the *cholerone*.'

"After having reproached physicians, who were not willing to risk their lives by making any autopsy on the cadavers, for the disease is highly contagious, and adding that it is 'one thing to speak about death and courage, and another is surely to die,' he gives a very interesting explanation why cholera becomes diffused and contagious. 'Because the worms, offended by the stench of the cadavers of their brethren, try to escape from their place, and in so doing, violently assail the belly, stomach, and throat, causing the choleraic symptoms, and also death, according to the intensity of the assault, as already described above.'

"Leonard, not yet content with having done so

much good for humanity, sacrifices all himself . . . and suggests remedies indicated to pacify and replace the worms, and to kill those who are enraged when they threaten our lives with deadly assaults, viz.: 'For cholera and cholerine, strong coffee, olive oil, rum, bitter decoctions, etc. For the *cholerone* . . . according to the strength of the patient.' These points constitute his secret nostrum, *discovered by chance* and *much tried*, which he will make known when 'asked by the authorities.' He is also 'willing to do this if public opinion will favorably receive and appreciate his bold publication.'"

A Japanese Girl's Toilet.

When a Japanese girl gets up in the morning, she washes her face, but does not have to dress her hair. That is attended to but once a week. The hair-dresser comes to the house and arranges her jet-black locks in the fashion for little girls of her age. So she has no trouble about her hair, and after her bath, the servant assists her to powder her neck with a small white brush. She puts a little red paint on her lower lip, and a little gilding in the middle. When she removes her sleeping-dress, she has on only a short skirt, which is simply a square piece of cloth, crape, or silk, tied around the waist. No other undercloth-ing is worn.

In making her toilet for the day, she first puts on a garment made usually of some coarse material, not very long, and reaching only to the waist, but with long sleeves. On the neck of this garment is sewed a deep fold of scarlet or some bright-colored crape or silk. A long, straight skirt of blue or red crape, silk, or wool, is tied around the waist; and over all three of these garments is worn the kimono, or dress. This is of some dark color, and made of coarse-spun silk or thick crape. For festivals and holidays, the dresses are of very fine material and very handsome. The outer dress is simply a wrapper, reaching to the feet, with very long and and wide sleeves, hanging nearly to the ground, and used as pockets. On each shoulder, a deep tuck is made which extends to the waist, thus making a little fullness for the skirt. But the dress has no gathers, and is straight all the way down. The neck is adorned with a wide piece of black velvet or satin, which reaches nearly to the waist, and the dress is crossed over the bosom and confined by a girdle. Over this is worn a very wide sash, a piece of brocaded silk or satin, stiff with embroidery in gold or silver, lined with soft silk, and fastened behind in a very large bow. When these are all on, but barefooted, or, if in cool weather, in white mitten-socks, made to reach only to the ankle, and with a place in which to put the great toe (just as mittens have a place for the thumb), she goes out to say "Ohaio," or good-morning, to her father or mother.—*M. C. Griffis, in St. Nicholas for March.*

A Japanese Baby.

M. C. Griffis thus writes in *St. Nicholas* for March:

When Kinè, the little Japanese baby, was one hundred days old, she was carried to the temple, just as some American parents take their little children to the church to have them christened, though Kinè's parents do not know or worship the true God. The priest wrote a prayer on a piece of paper and put it into the prayer-bag, which was small and made of red crape, embroidered in white flowers and drawn together by silk cords. This bag containing the prayer was the "guard from evil," and it is devoutly believed by all Japanese to have the power of keeping children from evil spirits, from delusion by foxes—for the people think that foxes can cheat or enchant people—and from all dangers. This little red bag was attached to the girdle behind. After bestowing a gift of money upon the priest, the parents and relatives returned home with the little girl and held a great feast in her honor. Kinè was carefully nursed, and carried on the back of a faithful servant, who fastened her there by a long string or bandage drawn around the waist and legs of the child, and crossed over the neck and shoulders of the maid. Her little head and bright eyes would bob on every side as her nurse walked or ran, and here she would go soundly asleep, or play as any baby would. She was never carried in any person's arms. Japanese babies seldom are. When Kinè's aunts or cousins wished to coax her away from her nurse or mother, they would hold their backs invitingly, and she would put out her little arms and go to one or another as she chose. Clasping tightly the neck of the favored one, and held there by the feet or legs, she would be as happy as if cuddled up in the arms. As the baby grew and began to walk, little sandals made of straw were put on her feet. These were fastened on by putting the great toe through a loop. When she was a year old her hair, which had been shaved, was allowed to grow a little, and then tied on the top in a very funny fashion. Every year it was worn differently.

The Advantages of a Good Dinner.

We have already referred to Dr. T. Lauder Brunton's lectures on "Disorders of Digestion" (see editorial, page 278), and we now note the following amusing and suggestive sentences. He had been to a good dinner, and he says:

"This dinner was a revelation to me; it not only showed me that cookery might rank as one of the fine arts, but taught me that it might be a powerful moral agent. I went to the dinner exhausted with overwork, irritable in temper, and believing that city companies were wasteful bodies, who squandered money that might be employed for useful purposes, and that they should be abolished; I came away feeling strong and well, with an angelic temper, and firmly convinced that city companies had been established for the express purpose of giving dinners, and ought on no account to be interfered with. Nor was the good thus effected of a transitory nature; the irritability of temper, which had disappeared in the course of dinner did not return; and the morning afterwards, instead of awaking with headache and depression, I awoke strong, well, and ready for work, and remained so for a considerable length of time. Nor do I think that mine is a solitary case. A succession of heavy din-

ners is, no doubt, injurious; but when the organism is exhausted, a good dinner, with abundance of wine, is sometimes of the greatest possible use. But there is one condition which must not be neglected, or otherwise the consequences will be anything but satisfactory; the dinner must be well cooked, and the wines must be thoroughly good."

An Anecdote of Garfield.

A year before his election, General Garfield could have been seen daily sauntering along Pennsylvania avenue, laughing, talking, nodding his head to this acquaintance and to that, without any obstruction to his progress in the shape of a sidewalk reception. Those who did not know him personally were familiar with his face and name. The ladies had heard his eloquence in the House—the street urchin had seen him at the base-ball grounds, shouting, with the eagerness of a boy, his pleasure or dissatisfaction as the game progressed. While a member of the House he often took occasion to run out into the suburbs of the city to witness this exciting sport. I remember one afternoon when he reached the stand erected on the grounds a few minutes after I did. I was leaning against the front rail of the platform, and, clapping me on the shoulder, he asked, "Who's ahead?" I gave him the information, and he thereupon became so interested in the game that he seemed unaware that his heavy weight upon my little body was, to say the least, inconvenient. He was constantly exclaiming: "Good catch!" "Fine hit!" "Oh! what a muff!" and other well-known extracts from base-ball language, and he soon grew so excited as to make me feel the effects. I thought it wise to move to a place of safety, and I finally succeeded in edging away through the crowd.—*From "Among the Law-makers," by Edmund Alton, in St. Nicholas for March.*

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the week ended February 7, 1885.

Long, W. H., surgeon, relieved at Detroit, Mich., to proceed to Chicago, Ill., and assume charge, February 4, 1885.

Godfrey, John, passed assistant surgeon, to proceed to Vicksburg, Miss., and Memphis, Tenn., as inspector, Feb. 6, 1885.

Bennett, P. H., assistant surgeon, to assume temporary charge of the service at Detroit, Mich., Feb. 4, 1885.

Williams, L. L., assistant surgeon, to report to the officer-in-charge at Detroit, Mich., for temporary duty, Feb. 7, 1885.

RESIGNATION.

Miller, T. W., surgeon, resignation accepted by the Secretary of the Treasury, to take effect March 1, 1885, Feb. 4, 1885.

PROMOTION.

Godfrey, John, passed assistant surgeon, promoted and appointed surgeon by the Secretary of the Treasury, from March 1, 1885, Feb. 6, 1885.

APPOINTMENT.

Williams, L. L., M. D., of South Carolina, having passed the examination required by the regulations, was appointed an assistant surgeon by the Secretary of the Treasury, Feb. 6, 1885.

Young Women as Athletes.

As evidencing the growing interest in hygiene, we are pleased to note that a number of young society women in this city have organized an athletic club, to be known as the "Women's Athletic Association." The members will include two or three sets of young ladies prominent in society. A hall is to be engaged, and a perfectly-appointed gymnasium will be the feature of the place. At the meeting at which the association was organized there was a heated discussion on the question of roller skating. Of the thirty-nine members, fourteen denounced the amusement as vulgar and prejudicial to health, and the opinions of several of the leading physicians of the city were read to back up their argument; but as twenty-five members voted in favor of rolling skating, a rink will adjoin the gymnasium.

The club members will also form a riding club in the spring, and daily rides will be taken through the Park in pleasant weather. The by-laws of the association state that gentlemen will not be admitted to the rink or gymnasium, and that only riding-masters employed by the association will accompany the members on their riding expeditions. Lady friends of members are to be admitted as spectators to the rink and gymnasium. Negotiations are being made with a view of getting the City Institute Hall, at Eighteenth and Chestnut streets.

Medical Missionary Work.

A convention of medical students was held, March 1, in Association Hall, in this city. A number of prominent physicians from this city, and several missionaries from foreign countries, attended both sessions. At the afternoon conference Rev. R. M. Luther, M. D., of Burmah, spoke of medical missions in India and Burmah; Rev. James Cameron, M. D., of the China Inland Mission, gave an account of the propagation of medical science in China and Thibet; Rev. Gerald F. Dale showed its progress in Turkey; and Professor D. Hayes Agnew, M. D., addressed the conference on "Medical Colleges in Heathen Lands."

In the evening, Rev. R. C. Atterbury, M. D., of Pekin, China; Rev. Arthur Mitchell, D. D., of New York; and Professor Theophilus Parvin, talked about medical missionary work in general. The purposes of the convention are to get medical students interested in the work, and to bring before the public the necessity of medical missionaries in foreign lands.

Sham Quinine.

Dr. C. Edson, of the Health Department of New York, says he is busy working up cases against a good many drug-shops that are selling adulterated quinine. A short time ago he caused the arrest of a druggist named Gebick, at 409 Third avenue, and he has been committed, under bail, to await the action of the Grand Jury. The Doctor, on analyzing the stuff sold as quinine, says

he found it contained 50 per cent. of sugar of milk. Fifteen additional samples, from as many different druggists, are now being analyzed by Professor Waller, of the Columbia School of Mines, and he is morally certain that the majority of these are adulterated with cinchonidia and quinidia; but no names will be given until the guilt of the parties is beyond dispute. It may be added that the supply of genuine quinine in this market is unusually large, and, as prices are comparatively low, there is all the less excuse for palming off on the public the spurious article.

Sanitary Council.

The Executive Committee of the Sanitary Council of the Mississippi Valley has fixed the date of the seventh annual meeting of the Council for Tuesday, March 10, proximo, and in the city of New Orleans. This is about a month earlier than its meetings are usually held, and the committee assigns as a reason for the change the probability of Asiatic cholera appearing in the country, and the uncertainty concerning national legislation on public health matters. Invitations are extended to all State and local health authorities in the valley, and to representatives of commercial and transportation interests.

Cerebral Studies.

"The Brain of Man: its Architecture and Requirements," is the title of a paper which Dr. A. L. Ranney, of New York, contributes to the coming March *Harper's*. This is a thoroughly scientific, yet highly popular, presentation of the latest knowledge of the brain, which should interest every one who has a brain. There is nothing more marvellous than the recent progress of science in this direction, and a number of diagrams help to make clear to the reader how far scientists believe the localization of function, and to what extent phrenology has a scientific basis.

Items.

—Dr. Eugène Bodichon, known chiefly in connection with his efforts to bring into notice the febrifuge qualities of the eucalyptus globulus, died on the 28th of January, at Algiers, aged seventy-four.

—In cirrhosis of the liver, Prof. DaCosta recommends the persistent use of small doses of hydrargyri chloridum corrosivum (gr. $\frac{1}{30}$ t. d.), with an occasional saline purgative to keep the portal circle unloaded.

—Knowsley Thornton has made eleven nephrectomies, all by abdominal section. All have recovered. This remarkable record is supplemented by four nephrotomies by the lumbar incision, three of which recovered.

—In the *Centralblatt für Gynäkologie*, Dr. Roth regards globus hystericus as due to a paræsthesia of the sympathetic. And as the pellitory root has been found useful in paralysis of the tongue and pharynx, the author was led to try it in globus. He gives from ten to twenty drops of tincture of pyrethrum four times a day. He reports six cases in which he employed it.

—We learn that a meeting of the citizens of East Boston was recently held with reference to the erection of a memorial to the late Dr. Thorndike, and that action was taken looking to the building of a public hall to be named after the deceased surgeon.

—In Prof. Bartholow's experience, metrorrhagia produced by fibroids or fungous granulations is much more decidedly held in check by diluted sulphuric acid than by ergot; while menorrhagia dependent upon ovarian excitement is generally more quickly relieved by bromide of potassium.

—In a case of chronic psoriasis of eleven years' duration, and which had during this time baffled all treatment, Prof. DaCosta placed the patient, a young man of 22 years, on Donovan's solution, gtt. x. t. d., to be increased to gtt. xx: t. d.; the object being to produce the full physiological action of the remedy.

—Sir Joseph Lister, Bart., has been appointed by the Emperor of Germany a Knight of the Order Pour le Mérite for Science and Art—an honor very rarely conferred. Professors Koch and Pasteur have recently been elected Corresponding Members of the Academy of Sciences in St. Petersburg.

—In a paper upon butterine, read before the Society of Arts, it is stated that in 1883 over 40,000 tons of that product were imported into England from Holland, the factories at Oss sending 150 tons a week. The latest improved butterine consists of oleomargarine, milk, vegetable oil, and real butter.

—On January 27th, at the West London Hospital, Mr. Swinford Edwards ligatured six large hæmorrhoids in a woman aged fifty. As she was the subject of aortic disease, it was decided not to administer an anæsthetic. One minim of a 4 per cent. solution of cocaine was therefore injected into each pile at the muco-cutaneous junction, after which the entire surface of the mucous membrane at the lower part of the rectum was painted over with a like solution. The operation, which lasted twelve minutes, was almost painless, the patient only slightly feeling the last incision. Twenty-five minims of the solution of cocaine were used in all.

—The Faculty of Medicine of Paris has awarded the prix Châteauvillars to Dr. Constantin Paul for his work entitled "The Diagnosis and Treatment of Diseases of the Heart." The Academy of Medicine has divided that portion destined for prizes of the Morbinne legacy among the following gentlemen: Dr. A. J. Martin, 4,000 francs, for his work on the "Civil Sanitary Administration in Foreign Parts and in France;" Drs. Straus and Roux, 2,000 francs each, for their cholera researches at Toulon; Dr. Van Morris, of Dunkirk, 2,000 francs, and to Dr. Amat, military surgeon, 500 francs, for their memoirs on the influence of sea-bathing in the treatment of scrofula in children.

DEATH.

CONNER.—February 3, 1885, 9 a. m., in Palmer, Illinois, Amy Lulu, infant daughter of Dr. J. J. and Mrs. M. E. Conner, of congestion of the lungs, aged 1 year, 4 months and 24 days.

LECTURE.

CLINICAL LECTURE ON DISEASES OF WOMEN, DELIVERED AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

BY PROF. T. GAILLARD THOMAS, M. D.

Reported for the MEDICAL AND SURGICAL REPORTER.

PREMATURE MENOPAUSE; THE OPIUM HABIT.

GENTLEMEN: Our first patient to-day is Mrs. Fanny D——, a native of Germany, and thirty-six years old. She has had two children and one miscarriage; but has been a widow for ten years. Her last pregnancy (when she had the miscarriage), occurred fourteen years ago, and she says she has now been sick for three years. I want you to observe the countenance of this patient carefully, for its characteristics are very significant; and I am sure that any good practitioner, with a fair amount of experience, would have no difficulty at all in arriving at quite definite conclusions concerning such a face, without asking the woman a single question.

Now, for the history which she gives of herself: Three years ago, she says, her courses stopped, and they have never reappeared since. In addition, she began to have severe cramps about the abdomen, and these have steadily continued, while she has also suffered from a terrible sensation in the hypogastric region, which she cannot describe, but which makes her feel, she says, as if "there was a large hole there, which never seems to get filled up." I do not wonder that she is not fully able to describe this feeling, as no writer with whom I am acquainted has ever yet succeeded in giving an adequate description of it. It is at the pit of the stomach, where is situated the solar plexus, which the old writers used to graphically call the *cerebrum abdominale*, that one experiences the pangs of nightmare after a late supper, and that the intemperate man feels the alcoholic craving, which can only be satisfied by resorting to his accustomed stimulus. It is this great ganglionic plexus which constitutes the origin of the sigh, and which gives rise to those feelings of peculiar weight and oppression which we experience when suffering from any disagreeable sensation. Under ordinary circumstances, however, we are entirely unconscious of the existence of any such *cerebrum abdominale*.

On inquiring if the patient has any additional troubles, we find that she has considerable abdominal enlargement, her person being fully the size of that of a woman at the end of the eighth month of pregnancy, or who has an ovarian cyst of eighteen months' growth. She suffers, also, from frequent epistaxis and headaches of great severity; and this is all, except that all the time she feels utterly miserable and unhappy. This melancholy and depression are so profound that she says her only wish is to die; and you notice that even now, while she speaks, she is weeping, which the friend who accompanies her here tells me is a thing of constant occurrence.

Here, then, is a woman who was perfectly well up to three years ago, when something happened which she laid great stress upon, viz.: the cessation of the menses.

In consequence of real or imaginary suffering she began taking morphia. At first the doses

were small, but afterwards she gradually increased them, until for the past two years and a half she has actually been taking ten grains of sulphate of morphia a day, or seventy grains a week. Each week, she says, she pays $3.50 for the drug, which must be no inconsiderable tax upon her resources for a woman in her position in life.

You will find opium-eating very common in patients suffering from uterine or ovarian troubles. On account of the painful symptoms which they experience, they take at first a quarter of a grain of morphia night and morning. After a time it gives rise to those peculiar sensations at the pit of the stomach, of which I have spoken, and to relieve which an increased quantity of the drug must be taken. The habit is like a leak in a dam, which, if left to itself, will result in the sweeping away of the whole structure, and thus the vice rapidly progresses until the individual is a complete slave to it. When what is known as the opium craving is once experienced, its demands become almost irresistible.

What has made this woman an opium-eater seems to have been the early occurrence of the menopause. At that time she probably suffered from certain neuralgic pains incident to the sudden and premature stoppage of the menstrual function, and for the relief of these she began taking the morphia. In consequence of the effect of the drug upon the system, peristalsis was stopped in the intestines, and the gaseous disturbance, which, when I practice percussion here, you will observe, is the cause of the abdominal enlargement which has been noted.

You see before you, then, a perfect picture of opium-eating; and in view of the melancholy results here so apparent, I cannot too earnestly caution you against fostering such a habit in your patient. Especially would I warn you never to instruct a patient in the use of the hypodermic syringe. This is the most dangerous method of taking opium, and most of you would, no doubt, be astonished if you could know how many physicians have become addicted to its use in this way.

It is next to impossible for patients of this kind to be cured by the exercise of their own wills, and, therefore, I will recommend this woman to enter the establishment of Dr. Mattison, of Brooklyn, where such cases are treated with great success, and where, as the Doctor has informed me, the large proportion of patients are physicians who have acquired this unfortunate habit. I have not time to dwell upon the treatment that would be prescribed for this patient in this institution; but will only mention the fact that the opium would be stopped entirely. If this were done for one month, I am confident that the abdominal cramps would disappear, because the opium craving would be gone. When an individual gets in the habit of taking hypodermic injections of morphia for the relief of supra-orbital neuralgia, for instance, the neuralgia is sure to come on when the opium-craving makes itself felt, and it will not be relieved until the craving is satisfied with more morphia.

A patient of mine suffering from disease of the ovaries and the fallopian tubes became accustomed to using 70 grains of morphia a week by hypodermic injections, and I decided to remove the affected organs. After the operation, she was not allowed the smallest particle of the drug in any form for six weeks, and when I last heard from her she was entirely cured of the opium habit. There is no other disease present in this case except the opium habit, and therefore, I think, the patient ought to be treated in some such institution as that of Dr. Mattison. If she will consent to adopt this plan, I am confident her pains will all be removed by the removal of the remedy which she takes for them, and I trust that she will come back to let us see the result at the end of six weeks.

PREMATURE MENOPAUSE MISTAKEN FOR PREGNANCY.

Our next patient is Mrs. Theresa K——, thirty-one years of age, and a native of Ireland. She is married, and has had two children and two miscarriages.

Miscarriages, as I have previously had occasion to remark, are exceedingly common, and it is a rare thing to find a woman who has had five children without at least one miscarriage. It is not at all uncommon to find, as here, the miscarriages equal in number to the births at full term. There must, therefore, be an enormous loss of human life from this cause.

The history which this patient gives of herself is as follows: She has not had her courses for eleven months, and when they stopped, eleven months ago, she thought she had become pregnant. The reasons which led her to suppose this, in addition to the cessation of the menses, were, sickness in the morning, enlargement of the abdomen, pain in the back, and longing for unusual things, such as she had noticed in her former pregnancies, irritation of the bladder, and, finally, movements like those of a fœtus. She felt perfectly certain that she was pregnant, and in a healthy married woman, thirty years old, who

had had two children and two miscarriages, and who, consequently, ought to know, there certainly was every reason to suppose that such was the case.

Could the rational symptoms have been more complete? If she had consulted you at the fourth month you would have told her, as I would have done, that she was pregnant; and you would have had a perfect right to do so. Yet the real truth in this case is, that the woman reached the menopause eleven months ago, notwithstanding the fact that she was only thirty years old. There cannot be the slightest doubt, therefore, that all of the symptoms which she has noticed, with the exception of a single one, the abdominal enlargement, were simply the effect of the imagination.

The signal of pregnancy appeared in the cessation of the menses, and all the rest followed as a natural consequence. The abdominal enlargement, which is real, of course lent additional coloring to the idea of pregnancy; but this, I find, is simply due to the increased development of adipose tissue, which so frequently characterizes the menopause. It is, no doubt, from this circumstance, as well as the fact that imperfections in the complexion connected with the function of menstruation often disappear at this time, that the expression, "fat, fair, and forty," had its origin. The abdomen here is fully as large as in the case of the patient who was last before you; but the uterus, instead of showing any increase in size, has already become considerably atrophied, so that the canal is less than two inches in length. Still, you must not forget that notwithstanding the uterus is not enlarged, the woman may yet be pregnant. A few weeks ago, I had the opportunity of showing you a negress upon whom, two years ago, after bringing her before the class here, I operated successfully for the relief of abdominal pregnancy at the Woman's Hospital. With the possibility of such a condition in view, I therefore made a careful examination in this case, and the result enables me to exclude abdominal pregnancy here.

These cases of mistaken pregnancy sometimes place the physician in a very unpleasant situation, and entirely without any fault of his. The only way to avoid such mistakes is by making a physical examination, and this, as a rule, it is not advisable to do unless it is particularly requested by the patient and her family. There is one point to which it may be well to call your attention in this connection, and that is, that women who have unlawfully exposed themselves to the risk of becoming pregnant are exceedingly apt to imagine that they are *enceinte*. In some instances they become really monomaniacs, and it is almost impossible to convince them that pregnancy does not exist. In our present patient the imagination has worked in a different way, and it is in cases like this in private practice that so much trouble is often occasioned the physician. The more wealthy and influential such a patient is, the more liable is he to be abused if it turns out that she is not pregnant. When called upon to express an opinion in the early part of a supposed pregnancy, you should always say that upon the end of the third month no one can decide the matter by even the most careful examination.

PELVIC HÆMATOCELE.

Our last patient to-day is Susan B., 42 years old, and a native of England. She is married, and has had one child, sixteen years ago. She has never had any miscarriages. She states that she was confined to bed for six months after her child was born, and that the doctor who attended her called her illness inflammation of the bowels. Her present trouble, however, has only been experienced during the last ten months. One night, ten months ago, she says, she twisted herself in bed, and felt a sharp pain in the left side, low down. It was not at the time of her monthly sickness; the flow having ceased two weeks previously. Since this "twisting," she has never been well. She was not confined to bed at first, but she afterwards had to take to her bed, and the physician whom she called in gave her an abdominal bandage. She remained four months in bed, and during the last six months has suffered so much pain that she has been obliged to remain more or less of the time in bed. During this period she has always had her monthly sickness regularly; but she does not suffer at such times any more than she does at others. In addition to the pain she says she feels very weak and miserable.

This is certainly a very curious history. The attack which followed the birth of her child sixteen years ago was probably one of pelvic peritonitis, and it occurred so long ago that it need not concern us now. After that the woman became perfectly well, and remained so until ten months ago, when she wrenched herself while in bed, since which time she has been in constant suffering. Without a physical examination it would be impossible to draw any deduction whatever in such a case as this. Even after having made a physical examination, I am not willing to make a positive diagnosis; but I will, at all events, tell you what was found, and the most

probable conclusion to be derived from the existing condition of affairs. On introducing my finger into the vagina, I ascertained that the cervix was drawn up under the symphysis pubis, and pressed against the bladder; while back of the uterus there was a hard mass, not very sensitive to the touch. Conjoined manipulation showed this mass to be large and wholly immovable. It was this which was pushing the uterus forward and against the symphysis pubis, and it also pressed posterioriy against the rectum.

When the patient wrenched herself in bed, as she has told us, she probably ruptured one of the utero-ovarian veins, and all through the night there was more or less outpouring of blood. A large mass of coagula formed, and the result is this pelvic hæmatocele from which she has been suffering for the past ten months. This condition results more frequently from rupture of the utero-ovarian veins than from that of any other. Such an accident is liable to occur from any unusual strain, just as rupture of the blood-vessels in any part of the body. Quite recently I saw an account of the death of the most noted fencer in Paris from cerebral apoplexy, after engaging in fencing practice for half an hour; yet at the autopsy it was found that there was no diseased condition of the arteries whatever.

I have said that I believed this mass back of the uterus to be a pelvic hæmatocele; but let us suppose for the moment that it is not this. What else could it be? *First*, could it be a fibroid, which has perhaps prevented this woman from child-bearing for sixteen years, and the attachments to which she wrenched while turning in bed ten months ago? As to the failure to bear children, I think the torn condition of the cervix which exists in this case offers the more satisfactory explanation; and as to the wrenching of the attachments of a fibroid tumor, this would not have given rise to constant pain for ten months. Last year a patient consulted me on account of a pelvic tumor, which I made out to be a uterine fibroid; but not long after she came under my care she passed a large quantity of clots by the rectum, and the tumor disappeared. It was, therefore, simply a pelvic hæmatocele. Such I believe to exist here.

What, then, shall we do with our patient? My only advice to her will be to let herself alone and stop going to doctors, as time will certainly cure her. In private practice, however, such a patient would expect some relief, and it would, perhaps, be well to use the faradic or galvanic current twice a week. There is, no doubt, a neuralgic element in the trouble, from pressure upon the nerves, and this would be relieved by such a course of treatment. Some of you would, doubtless, like to ask why I don't insert a bistoury, or, at all events, an aspirator needle into this mass, and relieve the patient at once. There is a time in the course of almost every medical man when he is anxious to plunge his knife into almost everything that offers the slightest pretext for such a procedure; but I have gotten past that period now. These pelvic hæmatoceles cannot be interfered with without a great deal of risk to the patient, and, consequently, I think this woman had better "rather bear those ills she has than fly to others that she knows not of."

Communications.

THE INCANDESCENT ELECTRIC LIGHT FOR THE EXAMINATION OF THE THROAT, NOSE, EYE, AND EAR; AN ELECTRIC OPHTHALMOSCOPE.

BY LOUIS J. LAUTENBACH, M. D.,
Of Philadelphia.

(*Concluded from page* 298.)

It may not be uninteresting, nor is it without the scope of this paper, to consider the various forms of incandescent lamps, and the means of generating the electricity suitable thereto. A very good opportunity of observing the different varieties of lamps was afforded at our Electrical Exhibition a few months ago. Of the numerous incandescent lamps exhibited, it will be necessary to call attention to but a few. In the Bodein lamp, exhibited by Messrs. Queen & Co., the incandescent filament is in the form of a straight bar placed at right angles to the platinum poles. The intensity of current required is low. In the Weston lamp, the filament is a series of undulatory curves; in the Bernstein lamp it consists of a hollow cylinder of carbonized woven silk, shaped like a U, with long arms, requiring, to produce whiteness of light, a very high tension current; in the Edison lamp, it consists of a fine carbonized long armed U, requiring, also, a high tension; in the Swan lamp, it consists of an elongated U, with a round loop situated within the curve. This loop is not present in their lights less than 40 volts; in the Baudet lamp the filament is quite broad in cross section, and is U-shaped; it requires considerable quantity of current of low intensity.

In my work, I have used the Swan and Edison lights, as well as the small lamps of Dr. Starr

(obtained at S. S. White's dental establishment). The Swan light used by me was a nine-volt lamp of slightly more than two candle power; the filament a slight curve 6 mm. in length. The Edison light, which was placed at my disposal through the kindness of a friend, was a 16 c. p. 95-volt lamp, the arms of the U-shaped filament being 7 cm. in length, and separated 2 cm. from one another. The Starr lamps were both of them of about 1½ c.p., the one being a 3.8-volt lamp, the other slightly less; the filaments were slightly curved, one 4 mm., the other 2.5 mm. in length. The employment of the electric-light without the use of any lenses, will often prove satisfactory, the objection to its use in this way being that with the smaller lamps employed the illumination is poor, and the image of the incandescent filament is quite small. A very important question which must be here considered is the production of the electricity to work the lamp. How are you going to obtain it? from a chemical battery, a dynamo, or from either one in connection with a storage battery? Hoping that our electric-light companies might be able to furnish it, I inquired at the offices of the Maxim and of the Brush Cos. At the Maxim's office I found them willing to supply the entire plant, consisting of the lamps, with a dynamo machine to supply them; it would, with the necessary engine, cost several hundred dollars. They were not able to supply lights from their office, but hoped that they would be able to do so some time in the future. At the office of the Brush Company, who own the American rights of the Swan light, I found that they would put in the lights with the dynamo, but that they were engaged in the perfection of storage batteries, which were to be supplied from their arc-light wires. They thought the problem of supplying the incandescent light was in a fair way of solution; that progress was being made from day to day. This company is at the present time supplying the basement of John Wanamaker's Thirteenth Street store with some seventy 8-c.p. Swan lamps by means of the current from a secondary battery, charged from their arc wires. The examination of the lamp on December 6th, 1884, showed it to be a Swan loop lamp, the straight arms of the U being 2.5 cm. long and 2 cm. from one another, the loop being, therefore, 2 cm. in diameter. The light was of a decidedly yellow color, the intensity of the current being too low to attain the desired whiteness, the light, however, being steady and quiet; the light given forth December 10th was a nearer approach to whiteness.

Not desiring to purchase a plant, I endeavored to employ the chemical battery, and in a measure succeeded. The Grenet battery, because of its high intensity, appeared desirable, but unfortunately the elements soon polarize and its efficiency rapidly diminishes. The battery requires considerable attention; the zincs must be removed from the liquid after using, they must be kept clean and freshly amalgamated, the liquid must be frequently renewed.

The Bunsen battery has also been used for electric lights. It is a battery which in its practical workings is of comparatively low intensity, and is very dirty, too much so to have in one's office. At the Electrical Exhibition it was used to furnish the current for three small microscope lamps of about 1 volt each. Two gallon Bunsen cells were employed, the liquid being renewed but once during the course of the Exhibition, the lamps being used one or more hours every day for some 35 days. The light, because of the low intensity of the battery, was decidedly yellow.

The Leclanché battery is an open circuit battery, also of low intensity. Its employment is attended with indifferent success.

The Fuller battery, as modified by Dr. Starr, is also an open circuit battery, but unlike the Bunsen and Leclanché, is of high intensity, each cell having an electro-motive force of almost 2 volts. This battery has been used for intervals throughout the day for more than three months, without requiring renewal of the plates nor recharging.

The bisulphate of mercury battery has been employed, but runs down too rapidly.

For the 2½ c. p. 9 volt Swan lamp, I employed 6 to 12 half-pint Grenet cells, coupled for intensity, giving me, therefore, when the battery was fresh and in perfect order, an intensity of about 20 volts. I found that this battery would answer fairly well, using it from 30 to 45 minutes per day, actual working time, for about a week. If after this it was used without renewal of the fluid, it could not be depended upon, the lamp perhaps burning well for a moment, and then becoming dull red.

The 2½ c. p. Swan, when supplied by three half-gallon Fuller cells, gave a fairly good light, apparently steady after the battery had been used for more than three months. Had I been able to employ four of these cells, I do not doubt but that the whiteness of the light would have approached, and perhaps equaled that obtained from twelve fresh half-pint Grenets.

For the 1½ c. p. 3.8 volt Starr lamp, I made use of four Grenet cells, half-pint each, and found

the light thus obtained of a beautiful whiteness. When, however, the battery had been employed for about thirty minutes daily, after six or seven days the light became yellow and not to be relied upon, the battery requiring fresh fluid.

The 16 c. p. 95 volt Edison light used by me, was supplied from a dynamo machine, and gave a most beautiful light.

Objections which have been urged against the employment of the electric light in examinations of the human organs are: first, the great heat; secondly, the intensity of the light; third, the sharp shadows occasioned; fourth, the presence of the sharp image of the incandescent filament wherever the light is thrown; fifth, its unreliability; sixth, its expense.

Taking up these objections seriatim, we will discuss first the question of the excess of heat. The incandescent electric light is peculiarly free from appreciable heat, provided the lamp has been well made, the vacuum being good. This is because there is no combustion. There is nought but an incandescent filament of carbon suspended in a vacuum. There is in fact so little heat created by the well-made lamp that it was only with difficulty that the rhinoscopic mirror could be heated sufficiently by the 16 c. p. 95 volt Edison, to prevent the deposition of moisture.

The second objection mentioned was the intensity or the brilliancy of the light. As yet, this has caused me no inconvenience. On one occasion I used the 16 c. p. 95 v. Edison steadily for an hour, giving forth a most brilliant bluish-white light, using it for the examination of a friend's eyes at least half that time, with a peculiar absence either of momentary blindness, or the least irritability occurring either in my friend's or my own eyes. This examination was made between 10 and 11 p. m., after a full day's work, and was followed the next morning by a feeling of utmost comfort in both cases. Since this was written, I at night examined the left eye of a friend with the 1½ c. p. Starr light continuously for more than an hour, not only with no inconvenience to either of us, but with a feeling of the utmost ease, comfort and rest being present the following morning. However, in examinations with an intense white light, one must be careful not to gaze directly at the filament before making the examination, as in that case it will be difficult, because of the inferior intensity of the reflected light, to study structures carefully. This is easily prevented by interposing a shade between the light and your own eye, being careful not to obstruct the rays falling on the reflecting mirror.

The sharp shadows, instead of being a disadvantage, are in many cases very serviceable. In order to understand the reason of this, we must consider the nature of the light we are dealing with. In the electric lamp, we can get the light from a full red to extreme whiteness, the color depending mainly on the intensity of the current. By using a current of sufficient tension to produce a brilliant white light, we obtain not only the light from the incandescent filament, but we also have a less intense violet-white light occupying the entire globe of the lamp. If we look at an incandescent light, this luminous sphere may be so intense as to prevent us from seeing the filament. When the electric light is reflected upon the membrana tympani, or upon the retina, or upon the structures of the posterior nares, we notice the image of the filament very distinctly; this is surrounded by the illumination derived from the vacuum (if it may be so called) surrounding the filament. This general illumination may be used as readily as gas-light; the special illumination being used for the throwing of shadows, thus studying elevations and depressions, and for the more particular study of the structures. By throwing the bright image at various angles, we can not only overcome the shadow at any particular portion, but we can also study the more carefully any variations from the general curvature of the parts. By means of the shadow the curvature of the turbinated bones can be studied much more satisfactorily. The shadow is also of considerable advantage in ear work, by giving us a more correct idea of any irregularities or variations in the curvature.

The fourth objection mentioned was the constant presence of the bright image of the incandescent filament, whether the light was used alone or in connection with a Mackenzie or a Tobold; whether beside a rhinoscopic or laryngeal mirror was employed. This fact has struck me as a peculiar advantage; it can be utilized. and will, I think, do us good service. As before mentioned, the bright image is surrounded by a less intense, but more general illumination. In this general illumination the lines of the image stand forth sharp and clear. This bright line enables us not only to study special structures, such as the macula lutea, the porus opticus, and the blood-vessels of the eye more thoroughly; but also if the image of the light be for part of its extent a straight line, it enables us to appreciate and estimate the degree of curvature of surfaces. Any elevation or depression present within the eyeball deflects the line of light; in posterior

staphyloma there is a marked change in the direction of this line; the depth of the porus opticus is revealed by the angular deviation of the line; a slight elevation of the nerve is easily discovered by the same means. By means of this line, the degree of retraction of the membrana tympani and its curvature can be studied; in rhinoscopic examinations, the line is valuable for the same reason. In laryngeal examinations I have not found it of any service.

The unreliability of the light is, I think, at present a valid objection. It is, however, not the lamp which is at fault, but the batteries. All chemical batteries are troublesome to have about, many of them give off acid fumes, and besides require considerable attention, running down rapidly; but by the employment of double fluid batteries, which are fairly constant, the light can be made to be much more reliable.

At present, electric lights are expensive, not because of the original cost of the lamp itself, but because chemical batteries are expensive. There is, however, some hope of relief. At the present time, our electric light companies are keeping up steam all day for the running of their dynamo-electric machines at night; the cost is but little less than it would be were they to run them all day. There is no reason why the current should not be produced during the day, and be stored up to be employed as necessary. There would be thus be a direct saving effected. Physicians could be supplied in this way at a moderate expense, and would then have a reliable current.

Considering, now, the advantages of the electric light, we have, first and foremost, its approach to daylight—its whiteness. In all other artificial lights, with the exception of the calcium light, the yellow rays preponderate. Yellow rays are a decided disadvantage. So apparent was this to Wm. R. Wilde* that in his treatise on ear disease he writes, "Shades of vascularity produced by inflammation or congestion, speckled opacities, minute points of morbid deposit, and slight ulcerated abrasions, want of polish, and loss of transparency, etc, cannot be detected" by the artificial light. In the white light of the incandescent filament there are no yellow rays, and the illumination resembles very strongly a good day-light. Of course, if the current traversing the filament be not of sufficient intensity, we may have yellow light. A second advantage is its brilliancy or intensity. This brilliancy is so intense as to allow us the more readily to recognize slight changes; this is marked in ear examinations. By means of this light the rhinoscopic image becomes very much more distinct, and the membrana tympani shows slight changes not otherwise discernable.

There are two advantages possessed by this light which are often considered objectionable. I refer to the fact of the light casting strong shadows, and the presence of the image of the filament in the part illuminated. Having above set forth why I consider them as aids in examination, it is not necessary to say more.

The vitiation of the air by gas is a material objection, which is particularly noticeable in the dark-rooms of our eye dispensaries. The electric light would render the dark-room more bearable, and the headaches, so frequently occasioned, would be much less common.

For the larynx and posterior nares, Dr. Starr's or Dr. Seiler's laryngoscope, or Trouve's photophore, or the lights placed in a Mackenzie or Tobold condenser, can be employed.

The illumination of the ear is best attained by means of a small lamp placed close to the speculum, the lamp enclosed in a shield or cap, with a small round opening; if a large lamp be at hand, the employment of the head mirror to reflect the direct rays into the ear is not to be despised.

For the eye, the direct rays obtained from a large Edison or Swan lamp reflected into the eye prove of great service. These large lights are not always obtainable, and then the electric ophthalmoscope, before described, will be found to be of use.

In purchasing a light, those ranging from ½ to 3 c.p. of not more than 10 volts, should be selected from. Lamps of larger size cannot at present be employed without the use of a very large and expensive battery. Filaments of the Bodein, Baudet, Edison, and Swan patterns should be employed.

To run lamps of the size indicated, requires from 2 to 16 half-pint Grenet cells, or 4 half-gallon Fuller cells. If the battery is to be employed for the light alone, the Fuller cells should be bought.

For general use, a Baudet 9 volt lamp run by 4 half-gallon Fuller cells, is, perhaps, the most satisfactory that can be purchased at present.

When we all can have storage batteries charged by our electric light companies, we will be able to employ lamps of greater length of filament and of greater resistance, and will then become the more conscious of the advantages of the electric light over all the other lights for medical examinations; and they will then be as common as the Argand burner is to day.

* Diseases of the Ear, 1853, p. 69.

I can do no less than acknowledge my indebtedness to Dr. Wm. H. Burk, for assistance kindly rendered during the course of this paper.

DILATATION OF THE SPHINCTER ANI IN DISEASES OF THE RECTUM.

BY WILLIAM F. WAUGH, M. D.,
Of Philadelphia,
Prof. Practice of Medicine, etc., Medico-Chirurgical College.

In several recent journals I have noticed dilatation of the sphincter ani recommended by French surgeons as a new method for the treatment of hemorrhoids. There is nothing new in the operation, which is described at length in Allingham's excellent work on rectal diseases, where the credit of bringing the method before the profession is given to Verneuil.

Allingham also points out as the cases for which dilatation is best suited, those in which the hemorrhoid is constricted by the spasmodic contraction of the sphincter; while in those cases which are attended by relaxation of the sphincter, the operation would only do harm.

Taking this for my text, I propose to show that in other affections in which we find spasm, or at least too powerful contraction of the sphincter ani, the operation of dilatation is of use, by putting the muscle at rest.

A butcher, aged 26, came to me for relief from an attack of piles. He had been subject to the disease for years; usually suffering from an acute attack twice a year. Some years since I injected a large hemorrhoid with carbolic acid for him, with the effect of giving him more pain than he had ever suffered previously, and confining him to his bed for nearly a week, while the hemorrhoid was not benefited in the least.

This time I found an internal hemorrhoid tightly grasped by a spasmodically-contracted sphincter. He experienced so much difficulty in emptying his bladder that he requested me to see if he were not affected with stone. Prof. Gerhard administered an anæsthetic, and I forcibly dilated the sphincter ani to its fullest extent, carefully going round the whole circumference until every portion of the muscle was completely softened, and the anus replaced by a large gaping orifice. Some soreness was felt after recovering consciousness, but the next day, and each day subsequently, he was back at his stand in the market, not losing an hour on account of the operation. For a few days he had to attend promptly to the calls of nature, but after that he regained full control over his rectum, and at no time was he seriously inconvenienced by its temporary paresis.

The pain of the hemorrhoids was at once and completely relieved by the operation; though I dare not go so far as the French surgeons, and affirm positively that it will never return. But the most striking feature of the case is that the difficulty in emptying the bladder was also relieved completely by the same operation; and it occurs to me that in some cases of vesical tenesmus dilatation of the sphincter ani might give relief. This is made more probable by the history of my second case.

The four-year-old son of the man whose history I have just given was seized with colic some weeks after his father had been operated upon. For ten days I gave him anodynes, laxatives, and carminatives; and in spite of them, the poor child cried with pain a large part of each day. Careful examination revealed no adequate cause for the pangs, and I was about to express the opinion that he had a foreign body impacted in his intestinal canal, when the mother told me he had to strain a long time before he could urinate. I endeavored to introduce a sound to examine his bladder; but not succeeding, on account of his resistance, passed my index finger into his rectum to obtain some information as to the state of his bladder in that manner. I found nothing abnormal; but on withdrawing my finger, he ceased his cries, and the colic was cured. Nor did the pains alone disappear, but the straining to urinate also ceased; and since then he has no difficulty whatever in promptly emptying his bladder.

A gentleman came to me for relief from a fistula in ano. It was a complete fistula, the external opening an inch from the anus and the internal so high up the rectum that I deemed it imprudent to cut. I therefore administered an anæsthetic and dilated the sphincter with my thumbs in the same careful and thorough manner as in the preceding case. I then introduced an elastic ligature, drew it tight, and fastened it with a pewter clamp. Unfortunately, I pinched the cord too tightly in the clamp, and three hours after the operation it broke, and clamp and cord came away. Owing to the pressing nature of the gentleman's business, it was a month before he could come to me to have the operation repeated. On examining the fistula, I found it had healed completely. As the elastic cord can hardly be held to have any healing properties, I can only believe that the cure resulted from putting the sphincter at rest by dilatation.

One other spontaneous cure of fistula in ano has occurred in my practice.

A young married lady came to my office with a

complete fistula opening on the labia majora, nearly two inches from the anus. A hard, cord-like sinus could be felt under the skin leading back to near the sphincter margin. In examining the case, I used a rectal speculum, which dilated the anus painfully. The day was appointed for the operation, the patient came, but the external opening had closed. Not having some apparatus I wished, she was told to return in three days. When I examined her then, I found the internal opening had also closed, and the sinus was disappearing. In a word, the fistula was healed spontaneously. Not until the preceding cases occurred could I comprehend why this fistula healed, as I had not even passed a probe through it, nor done anything else which could set up a curative degree of inflammation.

Of the effect of dilatation in curing simple fissure of the anus I need not speak at length; the merits of the procedure in this painful affection being well known to every physician. The close relation of the sphincter ani with the sphincter vesicæ is apparent. Both are supplied with nerves from the sacral plexus. It is impossible to produce voluntary contraction or relaxation of either without the other. Spasm of the one induces a similar condition of the other. Hence, the inference seems justifiable that dilatation of the sphincter ani would relieve spasm of the sphincter vesicæ; and this is borne out by the history of the first two cases related above.

Hospital Reports.

A CLINICAL LECTURE.

BY WM. H. WATHEN, M. D.,

Professor of Obstetrics and Diseases of Women and Children in the Kentucky School of Medicine.

Reported by ALLEN KELCH, M. D.

Sterility.

GENTLEMEN.—This woman, Mrs. P., 25 years of age, was referred to me by a professional friend. She has been married about four years, and has never been pregnant. She has until the last year been regular, both as to time and quantity, in her menstrual functions. Since then the flow has been diminished very much, at times only staining her linen. Otherwise there is nothing in the subjective history that points to any abnormal condition. She bears the appearance of a healthy woman, and she complains of no suffering. Her husband, a stout, vigorous man, says he has never had any constitutional disease, nor *any* disease of his generative system. Sexual connection has been perfect, both having desire and pleasure; yet after four years of married life she has not conceived—so there must be some fault with her or with her husband, which, it is my purpose to discover, and, if possible, correct. I feel an especial interest in this case, for the reason that this woman and her husband are anxious to have children, and, as a conscientious physician, appreciating the moral as well as the professional responsibility that rests upon me, it is my duty to do everything I can to bring about a successful result. The moral aspects of the subject of sterility may be matters of serious importance, and I wish in this connection to call your attention to the great evil of the present day, practiced in every station of life throughout this great country—the prevention of conception and the destruction of unborn life.

This is collateral to the subject which I desire to discuss, for the reason that people who practice the prevention of conception or abortion are, while potentially fertile, practically sterile. There should be no necessity for me to attempt to urge upon you the great moral and professional evil of practicing abortion, for that ought to be well recognized in all respectable society; however, let me remind you that there is a great obligation resting upon you in this particular, for the reason that you will be importuned by husband or by wife, by married as well as single, to produce abortion yourself, or to give directions by which others may accomplish it. Let me say to you, that no physician, under any conditions, without sacrificing his manhood as a physician, can countenance the production of abortion, and that it is his duty to discountenance it on every occasion. It would be an insult to your intelligence to dwell upon this subject.

But I will now refer to the habit of preventing conception, the line of demarcation between which and the destruction of unborn life, the moral philosopher can scarcely draw.

There is nothing about which the moral nature of woman is so warped as that which concerns her duty in regard to childbearing; women who are otherwise intelligent and moral, reputable members of society and of church, will not hesitate to persist year after year in preventing conception. You will often meet with women who will reason intelligently upon every other subject, but are deaf to all argument upon this. I would not detain you to speak upon this subject if you could find the proper consideration of it in text-books. It is a subject to which authors give too little attention.

The prevention of conception is a violation, not alone of the laws of morality, but likewise of the laws of nature; it is destructive alike of the morals of married life and of the physical and mental health of the husband and wife.

If we consider the history of this question, we find that the prevention of conception has been condemned and punished from the earliest history of the world: the fate of Onan, you well know, and his sin of withdrawal before his semen was deposited in the vagina, was the same that is now practiced everywhere. Numerous other instances are given in sacred history where God has punished mankind for the commission of this evil. The very first command God gave to Adam and Eve was, "Be fruitful and multiply, and replenish the earth." A like commission was given to

Noah, and many other instances might be drawn from sacred history. The Bible is full of evidence of the will of the Creator upon this subject, and that every violation of that will has been severely punished. In the New Testament, St. Paul advocates and urges the same doctrine. There is nothing that is more likely to result in disease, not only of the woman, but of the man, than indulgence in this practice.

I recall to mind a patient who recently consulted me, suffering from nearly all the multitudinous forms of reflex nervous disturbance, with enlargement of the uterus and a constant leucorrhœa.

The uterus, the vagina, and the vulva were in a hyperæsthetic condition, and her mind on the verge of insanity. Her husband has, for the last two or three years been insane. On inquiry, I learned that after the birth of their last child, now 12 or 14 years of age, they agreed that they would have no more children, and upon consulting with a *physician*, were advised to prevent conception by withdrawal before the emission. The moral effect of this upon the woman and the man is nearly identical with that resulting from masturbation. The physical disturbance is even greater when the organ is withdrawn at the beginning of the orgasm. The vasa defferentia remain partially filled, the connection being incomplete and unsatisfactory, and causing the husband to have a more frequent desire for sexual connection than is healthful. The failure to deposit the semen in the vagina doubtless leaves a state of congestion of the female organs that may sometimes remain until a repetition of this incomplete connection. A final result is engorgement, possibly displacements, hyperplasia, and kindred conditions, entailing various nervous disturbances of the system.

Pardon me, gentlemen, for this extensive digression.

Examination of the patient before us shows the uterus to be about normal in size, but the os uteri is small, and the cervix projects too far into the vagina, and is conoidal in shape. The immediate indications are that the sterility in this patient results from a fault in the woman, not only from this abnormal condition at once detected, but also for the reason that her menses are now materially lessened, indicating probably some ovarian incapacity; however, as soon as an opportunity presents itself we will make a microscopical examination of the semen of her husband, to determine whether it contains living spermatozoa.

The treatment of sterility is, of course, to remove the cause, if possible; and as a cause apparently sufficient exists in this conoidal cervix and contracted os, together with ovarian disturbance, we will direct our treatment to the removal of these conditions.

We will prescribe hot vaginal injections of two gallons of hot water every night during her intermenstrual period, and will give her the following prescription:

℞.	Ext. centuriæ benedic,	℈iss.
	Ext. ergotine,	ʒj.
	Ext. cannabis ind.,	gr. viij.
	Zinci phosphidi,	gr. j.

M. ft., capsulæ No. xxx.
Sig.—One three times daily.

Is it necessary to add that a change in the shape of the cervix must be made? The treatment formerly resorted to in order to accomplish this consisted of dilatation with sponge, seatangle, or tupelo-tents, or by slight division of the external os. This, experience has taught, is seldom successful, the os returning to its original size and shape, and the cervix remaining unaltered. Occasionally the shape of the cervix has been changed by amputation of a small portion; there is an operation that will accomplish this in nearly every instance much better and with less risk to the patient. I refer to rapid dilatation of the cervix by means of metallic dilators. I have been in the habit for several years of practicing rapid dilatation with Atlee's dilator, at my office, for sterility, dysmenorrhœa, menorrhagia, and metrorrhagia, and for the purpose of enabling me to make an application directly and easily to the lining membrane of the uterine cavity. The pain of the operation is trifling, and I have never seen the least unfavorable result. It is much safer than tents, for the reason that after their use we often have metritis or pelvic cellulitis or peritonitis. I have never had any of these complications after rapid dilatation. We will then first dilate this cervix to the full capacity of this dilator, which may open the os enough to allow semen to enter into the uterine cavity, and may also modify to some extent the shape of the cervix. If after a few months this woman does not conceive, and has not received material benefit in her local condition, we will then practice rapid dilatation with a large dilator, that will open the cervix as wide as an inch or an inch and a quarter. This is done by first introducing into the rectum an opium suppository, or by giving a hypodermic injection of morphia, after which the woman is placed under the influence of an anæsthetic, and the cervix dilated to the extent desired. This not only opens the os so that it seldom returns to its contracted condition, but changes the shape of the cervix, and if there be flexion tends to straighten that. When the circular fibres of the cervix are dilated, it is of course at the expense of the longitudinal fibres; thus it shortens, straightens, and entirely changes the shape of the cervix. Possibly in a few instances it may become necessary to make superficial quadrilateral incisions into the external os. This operation has been practiced many times by Prof. Goodell, of Philadelphia, with no unfavorable complication. You can dilate with Sims' large trivalve dilator, or the large-sized Ellinger's bivalve. If this treatment thoroughly done fails to produce fertility in this woman, then it is doubtful if anything can.

[The dilator (Atlee's) was then introduced, and dilatation to the full capacity made—Rep.]

(*To be continued.*)

—It has been determined to spend the very liberal sum of $600,000 in creating new scientific buildings in connection with the University of Turin. Half that sum will be provided by the Provincial and Communal Councils of the city, and the other half by the Government, with the sanction of the Italian Parliament.

PHILADELPHIA NEUROLOGICAL SOCIETY.

(*Continued from page* 303.)

Case 4. Dr. A. A. Y., male, æt. 65, resident of Hammonton, N. J. Examined the patient with Dr. S. Weir Mitchell on January 16, 1885. For the substance of the following notes I am indebted to Dr. Woodnutt:

History of patient: Family history excellent. He had always been strong and hearty during youth and up to 1865, though a hard-working farmer. An army life, and three years of extreme exposure prior to the close of the war, found him suffering in 1865 from sharp, wandering pains in the upper and lower extremities; never noticed, however, in the articulations. Loss of power followed in the right leg. Three years later suppurative arthritis attacked the metatarso-phalangeal articulation of the right great toe, and last phalanx of left ring-finger, sequestra coming away in each instance.

During 1870 the patient first noticed an œdematous swelling of the right elbow; following shortly upon this, the wrist-joint of the same arm gradually and painlessly enlarged. Then a distention of the capsule of the right knee-joint succeeded. The enlargement of the latter articulation was more rapid than either the wrist or elbow. Rheumatic pains in the joints accompanied the swelling and deformity.

The left limb has been comparatively exempt from pain. Recently, however, the capsule of the knee-joint has become distended and elastic. The elbow tumor has diminished somewhat in circumference during the past four years.

During the past year the distal phalanx of the right index finger has gradually atrophied, without inflammation, and is entirely wanting. The nail and finger end are normal, though somewhat shortened. Pain at present is chiefly in both feet, paroxysmal and erratic, often attacking corresponding points on the legs.

The present appearance of the right elbow and left knee joint enlargements exhibit an irregular nodulated hypertrophy, bearing no resemblance to normal joint outline, and consisting chiefly of osteophytes and abnormal increase of synovial fluid. Motion preternaturally free in all directions; structure of joints apparently entirely destroyed.

Remarks.—The joint lesions first appeared in this patient after ataxia had become established. The appearance of the affected elbow and knee is that of an enormous nodular hypertrophied mass of bone, doubling their normal circumference, associated with synovial distention of the capsule. Osteophytes readily movable within the capsule, and varying in size from a pigeon's egg to that of a turkey's.

The atrophy of the distal phalanx of the right index finger is especially to be noted, it being the first instance of complete absorption of the diaphysis of bone that I have had an oportunity of observing.

Case 5. W. H. McC., male, æt. 38, married. Admitted to the Orthopœdic Dispensary of the University Hospital in July, 1883.

Hereditary history excellent; no evidence could be obtained of articular disease, rheumatism, or phthisis, in any member of his family. He presented at date of examination the appearance of a healthy, well-nourished man. He has always worked industriously at his trade of plumber. A moderate drinker. He had constitutional evidence of syphilis, following a chancre contracted in 1863.

The patient attributes the present enlargement of the right ankle-joint to an injury received while working in a cramped position. Following this strain, the ankle became suddenly discolored and swollen, bursting the buttons from his shoes. He was incapacitated for work during the succeeding four days; at the end of a week, the discoloration and swelling had about disappeared. His attention was then first directed to a bony enlargement of the right ankle-joint. This slowly and painlessly increased in size, without any appreciable interference with locomotion. At present examination, the enlargement resembles a simple hypertrophy of the lower epiphyses of the tibia and fibula. The outline of the joint is globular, with slight elasticity of capsule. No pain or reflex muscular spasm.

Record of Spinal Symptoms.—Complains of darting pains about hips. Has difficulty in walking at night. Sways with closed eyes. Complete absence of patellar reflex on both sides. Dr. Horatio C. Wood saw him with me in October of 1883, and pronounced him ataxic.

Remarks.—This case presents an arthropathy that apparently followed a direct traumatism to the affected limb. From careful interrogation, I determined that the acute swelling and ecchymosis resulted from rupture of a varicose vein, inasmuch as these were numerous, and greatly engorged, about the affected ankle. The first attracted his attention to the ankle, the deeper bony growth being detected when the active symptoms of subcutaneous swelling had subsided. The hypertrophy of the joint has increased the circumference four and a half inches over its fellow.

Case 6. A specimen of shoulder-joint arthropathy, lately removed at an autopsy held upon the body of a well-marked ataxic, has been referred to me by Dr. S. Weir Mitchell, to embody in this report. The joint had become suddenly and painlessly enlarged in the later stages of the the central lesion. It presented ante-mortem all the characteristic symptoms of a tabetic arthropathy; distention of the capsule, abnormal mobility, and the presence of osteophytes. The joint, upon examination, presented the following:

1. Cartilage covering head of humerus eroded; that upon glenoid cavity irregularly thickened.

2. Anterior margin of glenoid cavity worn away, allowing the head of bone to rest in position of forward dislocation.

3. Osteophytes abundant about junction of capsule with anatomical neck. Marked relaxation of ligamentous structures, and distention of capsule.

4. General hypertrophy of epiphysis, somewhat nodular at margins. Evidences of hydrarthrosis.

The practical deductions to be drawn from a clinical study of the above somewhat anomalous cases, may be briefly summarized as follows:

Period of Development.—1. The tabetic arthro-

pathies may occur independently, or precede the active symptoms of locomotor ataxia.

2. They occasionally develop suddenly, late in the course of a posterior spinal sclerosis.

Nature of Lesions.—The peripheral expression of central nerve irritation is characterized by the following changes found in the structure of the various articulations.

1. A chronic asthenic hyperæmia of the synovial membranes; a hydrarthrosis.

2. An interstitial atrophy of the epiphyses.

3. A fungous or rarefying epiphyseal hypertrophy.

4. The formation of osteophytes and bony stalactites.

These various joint expressions characteristic of the spinal arthropathies may exist separately; but are usually combined in the same subject.

Differential Diagnosis.—They may be readily distinguished from the common inflammatory lesions of the epiphyses by the total absence of the reflex neural phenomena—*i. e.*, of pain, both reflex and local, the apprehensive state regarding joint movements and the reflex or tetanic spasm of the muscles, always associated with joint arthritis. Abscess is never directly associated with the arthropathies, unless incident upon direct traumatism.

They are more difficult to differentiate from malignant disease of the articulations; but a careful inquiry into the history and course of the lesion, and the presence or absence of central disturbance, are our most reliable guides.

Course.—The progress of the arthropathies is essentially chronic. Occurring early, not infrequently, in the history of the tabetic lesion, they slowly increase, with occasional exacerbations, and years elapse before fully matured. A rapidly developing arthropathy may be associated with the later stages of an ataxia. Their course is self-limiting, though never reparative.

Dr. Morris J. Lewis reported

A Case of Locomotor Ataxia with Loss of Teeth and Alveolar Processes.

The following anomalous case of locomotor ataxia has been under my care for three months in the Episcopal Hospital. He is now under the care of Dr. Henry M. Fisher, who courteously allows me to use the notes of the case.

Mr. A., æt. 45, a well-marked ataxic for over five years, presents the following history, some points of which seem well worthy of record. Nasal catarrh exists in several members of the family, including himself. During the war he was wounded in the hip and ankle slightly; the wounds healed kindly. He was confined for some time in Libby and Belle Isle Prisons, and since then has never felt strong. He denies having had syphilis. When 39 years of age he began to show the first symptoms of ataxia; these were diplopia, dizziness, and a staggering gait. One and a half years later he began to have lancinating pains in the extremities, and later in the bowels. Five years ago he began to have transient attacks of difficulty of hearing, and this has increased since then until about one year ago, when he became absolutely deaf.

He has always been constipated, and one year ago had slight difficulty in urination. Within the last seven months he has had severe gastric crises. Eyesight good until the last seven or eight months, except during the first year. Four years ago the symptom for which I present the case to-night first appeared. This was a loosening and a subsequent falling out of the lower wisdom teeth. No pain nor discomfort preceded this, and the teeth were perfectly sound. In fact he had an uncommonly fine set of teeth. After this his teeth gave him no trouble until about seven months ago, when the same change began in the upper jaw, causing the loss of every tooth except the right first molar, which still remains firm.

The sequence of these events appears to be as follows: First, the teeth loosen, then the gums recede, showing in places the alveolar processes denuded, the teeth then fall or are pulled out by the fingers, and finally the alveolar processes separate in small fragments, with slight suppuration, or are detached in larger pieces. The gum then heals. The largest piece of bone thus separated shows the sockets of three incisor teeth, and a portion of a fourth. The teeth show no absorption of their fangs, and are almost without exception perfectly sound. About four months elapse between the loosening of a tooth and the final healing of the gum.

Other points of interest in this case are as follows: The patient is extremely pallid; he has the ataxic gait, although this is not very pronounced. He cannot stand with eyes closed. The knee-jerk is absent, and has been for the last four years. There is no anæsthesia of the feet or legs, and the patient localizes touch fairly; there is, however, some analgesia. There is no retardation of sensation. Examination of the eyes shows external strabismus of both eyes. Pupils pinpoint for near accommodation, and relax for distant vision; no reaction to light. Ophthalmoscopic examination shows left eye-ground normal, and but slight atrophy of nasal border of right disk. His sense of smell and of taste is good. There are no lesions in any of his joints to be detected.

Dr. Lambert Ott presented a case of

Locomotor Ataxia with Charcot's Joints.

S. H., aged forty-five years, a traveling salesman. In 1866 he contracted chancre, no secondary symptoms following. In May, 1881, his present disease began with shooting pains in limbs and unsteadiness of gait. In November, 1883, I first saw him and diagnosticated his condition as locomotor ataxy. At the present time there is very little missing that goes to make up the symptom-group of this disease. In December, 1883, about two and a half years after the beginning of his trouble, he noticed a swelling of his left ankle. In the morning it seemed less, and in the evening it had increased to such an extent as to cause difficulty in taking off his boot. He had no pain, no impediment in using the joint, and had it not been for the swelling he would not have taken any notice of it. He thinks the swelling reached its maximum in two weeks, and there has been no great variation since, except that in the evening it is slightly increased. At present, his foot is moved normally, but when the back of the leg is grasped and extreme flexion made, crepitation is imparted to the hand; the

swelling is confined to the inner and dorsal surfaces of the ankle-joint, and feels bony. The joint measures in circumference one and a half inches, the leg at midcalf one-half inch, more than the opposite limb. There is no pain or tenderness on pressure or rough usage. He has been under treatment fourteen months, and has taken corrosive sublimate and chloride of gold and sodium. The electrical treatment at first was central galvanization and general faradization, and latterly the metallic brush, with the rapidly interrupted faradic current, with marked improvement.

The next paper was entitled,

Note as to the Comparative Effects of Active Voluntary Exercise, and of Passive Exercise by Massage, on the Production of Albuminuria,

by W. W. Keen, M. D.

At the request of Dr. Mitchell, I desire to call your attention, briefly, to one point of value in the use of massage, heretofore, so far as I know, unrecognized.

A patient, Mr. C. called upon me for relief from quite severe, constant, and long-continued pains in the calves of his legs. During the preceding year he had walked, as a matter of exercise, nearly 2,000 miles, and during the year before that had traveled around the world, making long rides and walks a marked feature of his trip.

In examining his case thoroughly I found that he had an albuminuria, the sediment forming (by heat and nitric acid) a varying bulk, on standing, of say from 3 to 10 or 15 per cent. This albuminuria I found, on further and most careful examination, to be curiously dependent upon exercise. This I finally tested in the following way: I put him in bed for three days and examined three and sometimes four specimens of urine passed at different times in the twenty-four hours. No albumen appeared at any time during these three days of rest. The last examination I made at his house at 1 p. m., on the third day. He emptied his bladder at that hour, and the urine was free from albumen. He then dressed and walked, by a pedometer, a measured mile. Immediately on returning he passed water which had about 5 per cent. of albumen. One hour later it had still a trace; two hours after the walk it was free. The next morning's urine was still free, but that passed at 9.30 a. m., at my office, after walking from his home, a mile distant, had again about 5 per cent. of albumen.

A few days later I employed massage. This was thoroughly done for forty to fifty minutes, by a most competent rubber. Examining the urine immediately before and immediately after the massage, both specimens were absolutely free from albumen. This I tested several times, with identical results.

This is a striking addition to Dr. Weir Mitchell's observations as to the resulting tissue changes induced by massage, and especially shows its value as a means of passive exercise without deleterious effects through nervous exhaustion. I believe the value of the massage to lie in the resulting stimulation to the muscular tissue, and the promotion of its nutrition without such changes of blood pressure and vaso-motor tonus in the muscular coat of the vessels, as induced the curious albuminuria after voluntary exercise above noted. The very probable nervous origin of albuminuria, as shown by its frequency in cases of long-continued nervous strain, and by the researches of DaCosta and Longstreth, would seem, also, to have a new confirmation by this observation. I regret that I did not at the same time observe the blood pressure by the sphygmograph, as it might have thrown additional light on the unusual facts above detailed.

My attention has also been called by Dr. Mitchell to an article on "Albuminuria as a Symptom," by the late Dr. Calvin Ellis, in the *Boston Medical and Surgical Journal*, 1880, vol. xxv., p. 388.

The following somewhat analogous cases are referred to by him: in one case (Dukes: "The Albuminuria of Adolescents," *Brit. Med. Jour.*, November 30, 1878, p. 794), a young man's urine was normal when in bed. On rising and taking milk only it would continue so, but after eating a piece of bread, the albumen would appear. As he improved while lying in bed, meat could be eaten without any change in the urine.

While this would look to digestive changes as a cause, the so-called post-cibal albuminuria, the following cases are more positive evidences of the effects of exertion in the production of albuminuria:

Edlefesen (*Berl. Klin. Woch.*, September 22, 1879), noticed in three healthy but anæmic men transient albuminuria after exertion. Leube (*Virchow's Archiv*, v. 72, p. 145,) examined the urine of a large number of healthy soldiers in the morning, and found it normal, but after a five hours' march or severe exercise, in June, July, and August, with a temperature of 54° to 77° F., it contained albuminuria in 16 per cent., though the amount was small, and never exceeded 1 per cent., and there were neither casts nor blood corpuscles. This could not be detected at a later examination, between 4 and 6 p. m. The same was seen under similar circumstances in army officers in connection with scanty urine, and also in nervous persons (Fürbinger, *Zeitsch. f. Klin. Med.*, 1, p. 345).

"It is most natural to suppose that its presence was owing, either to some variation in the blood-pressure, or to some change in the vessels. The rapidity of its appearance and disappearance makes it extremely improbable that there was any change in the vessels, and we are left with a variation of the blood-pressure. The view that the last might be operative seems to be supported by the statement of Ranke, that the blood accumulates in the muscles of a healthy man during exertion, while it is diminished in the organs which are at rest."

I may mention in the case of Mr. C., in the course of a year the albumen has become constant, though his exercise has been restricted to the least degree consistent with health; but the amount is never over a faint trace. At no time have any casts or blood been discovered. A prolonged sea-voyage is now being tried as a means of cure.

A paper was read by invitation on

Hysterical Affections of the Eye,

by George C. Harlan, M. D.

As it is well known, patients in the psychologi-

cal condition called hysterical, may not only present almost any symptom of disease, without the existence of any lesion to which such symptom could be referred, but sometimes make excursions termed the limits of classical pathology, and puzzle their doctors by originating symptoms that no possible lesion could explain.

It has seemed to me that the eye is an exceptionally pregnant seat of such affections, and that their occurrence there has hardly received the attention from neurologists, or perhaps even from ophthalmic surgeons, that might with advantage, be given to it. The accuracy with which eye symptoms may be analyzed, and the comparative certainty with which material changes in the tissues of this organ may be excluded, afford special facilities for the study of its functional, neurotic disturbances, which may often furnish the key to mysteries in other regions.

It is not my intention to trespass upon your time and patience by an extended discussion of this rather wide subject, but merely to direct attention to it by describing some of the symptoms of this class that have been met with in my own experience. As the shortest way of accomplishing this end, I will consider them in the anatomical order of the parts affected.

The lids are subject to both spasm and paresis of an entirely hysterical character. The former was well illustrated by a case recently published in the *Medical News*, in which violent and persistent blephrospasm, which had resisted other treatment for months, was cured at last by mental impression. The latter occurs in a singular form of transient paresis of the levator, occurring only on rousing from sleep.

The subjects of this affliction complain of a great difficulty, sometimes an entire impossibility, of opening the eye on awakening. In some cases this occurs always in the morning, in some even after a nap during the day, and in others only when aroused during the night, when perhaps the consciousness and will-power are regained less promptly. Such patients say that the lids seem too heavy to be moved by their own muscles, but after they have raised them with the finger, or bathed them in cold water, the difficulty does not recur until they sleep again. My attention was first called to this symptom some ten years ago, and I have met with so many cases since that I have come to consider it not very uncommon. Both eyes are usually equally affected, but in several instances only one was involved. In one of the latter now under my care, the affected lid has a slght degree of granular conjunctivitis, which could scarcely have other than a mental influence as a cause. With one exception, the subjects were all delicate women, some of them nursing. Of course, this is not a symptom to be lightly considered, without a careful investigation of the patient's general condition. The first time that I noticed it, it was one of the earliest indications of intercranial tumor, which, a few months later, caused the patient's death.

Singular action of the external muscles of the ball is so frequently met in nervous subjects that a well-known ophthalmic surgeon has discovered it to be the cause of nearly all the ills that nerves are heir to, and claims to remedy these ills by operating on the muscles. In fact, the external ocular muscles of hysterical patients are, in a large proportion of cases, not much better balanced than their minds, and, no doubt, decided results may sometimes be obtained by operating at the same time on both.

The most common form of this disturbance is insufficiency of the internal recti, which frequently occurs independently of any error of refraction. When very decided in degree, it may easily be detected by directing the patient to look at some small object eight or ten inches from the eyes, and then holding the hand before one eye. The covered eye, thus relieved from the effect of binocular vision, will deviate outwards. In some cases the preponderance of action is with the internal recti, and in others no two examinations made in different dogs will give the same result.

A spasmodic contraction of one muscle is more rare. I reported the following well-marked case some years ago (*Transactions of the Philadelphia College of Physicians*, '76):

Miss M., a little below par in general health, and of extremely nervous temperament, complained that frequently, and without special exciting cause, as at the dinner table, or at the opera, everything suddenly appeared double, and at the same time it was evident to her that she had lost control of the movements of one eye, which felt as if forcibly turned to one side. On closing the lids and pressing the ball for an instant, the symptoms would disappear. The acuteness of vision was normal, the balance of the external muscles correct, and refraction nearly unimtropic. The correction of an hypermetropia of 75 D. did not prevent the recurrence of the annoyance. Two other patients have complained of occasional transitory diplopia; in one case horizontal, and in the other vertical. These patients occasioned much anxiety at the time—one ten years, and the other about six months ago—but I have seen both recently, and they are in good health. In this connection may be mentioned two curious cases of non-ocular diplopia. In each the symptom persisted for several weeks, but was without physical cause, and disappeared without special treatment.

The case recently reported (*Med. News*) of hysterical mydriatis and paralysis of accommodation, occurring in one eye only, persisting for months, and finally relieved by mutual impression, is, I believe, unique. There can be no suspicion of deception here, as there is no known mydriatic whose effects can be made to disappear so promptly and completely as these symptoms did.

Paresis or spasm of the accommodation, is not unfrequent in neurotic subjects. The latter occurs usually, though by no means always, in connection with some case of refraction which acts as the exciting cause.

Retinal anæsthesia is a symptom which often occasions great annoyance to ophthalmic surgeons in testing refraction. Its subjects may at one moment have full asinity of vision, while at the next, with the same glass, it is very much diminished. They say that the letters become blurred and fade away after they have looked at them for a few seconds. The fact that this symptom persists under atropia shows that it is due, not to irregular action of the accommodation, but to exhaustion of the sensibility of the retina.

This condition of the retina makes the typical hysterical field of vision more restricted on the side that is recorded last in the testing. Such fields, the tracing used in discussion of which have afforded much entertainment to the curious, and rarely found the same at any two examinations. A patient recently presented himself at the Polyclinic with complete horizontal hemianopsia of the right eye only. There was complete blindness below the horizontal line. As the ophthalmoscopic appearances were normal, I suspected hysteria. At her next visit the hemianopsia had disappeared from the right eye and appeared in the left, still in the lower half of the field, but with an irregular border. It was several times transferred from one eye to the other, each time with a more irregular outline, and after a few weeks disappeared entirely, leaving the field in both eyes quite normal.

I have met with several cases of colored vision —blue streaks, yellowish, fogs, etc., of transitory character and evidently nervous origin.

Unsteadiness, or even apparent constant motion, of any object looked at, particularly print, occasionally occurs, and, not admitting of our physiological or optical explanation, may be classified as hysterical.

The most striking symptom, and the one that has naturally excited the most interest, is simulated blindness. For obvious reasons of expediency, this is usually monocular. At various times in the last ten or twelve years, I have reported four well-marked cases (*American Journal of Medical Sciences*, October, 1873; *Transactions of American Ophthalmological Society*, 1882 and 1884). Two were cured by exposure, and the others got well without ever knowing that they were suspected—possibly without having suspected themselves. One of them had a history of an attack of complete blindness, evidently of the same character, of both eyes occurring some time previously; and another such case has been reported by Dr. D. W. Agnew (*American Journal of Medical Sciences*, October, 1873).

Various tests have been devised for the detection of simulated monocular blindness. The one most used has been Grafe's pressure test. If the patient can be made to admit double vision when a prism is held before the well eye, vision with both eyes is proved. A very simple test suggested by Narlament may sometimes succeed, and, in his hands, has proved conclusive even as legal evidence. It displaces the axis of an eye by slight pressure upon the ball with the finger, and shows the suspected person two small dots on a piece of paper. If he says there are four, he is at once convicted. It must be remembered that these tests do not show how much the eye can see, and do not even prove useful vision. This can sometimes be done by an equally simple test suggested by Javal. He causes the person to read while a ruler is held three or four inches from the face, and directly in front of the nose. As part of the print is concealed from each eye by the ruler, it can be read continuously only by the use of both. An elegant but most difficult means of detection is afforded by the stereoscope (Schweigger, *N. Y. Med. Jour.*, Feb., '66). A test that has proved very satisfactory in my hands, is one that I first employed in a case reported in the *American Journal of Medical Sciences* for October, 1873. It consists in placing a strong convex lens before the well eye, and requesting the patient to read prints held considerably beyond its focal distance. If he reads at all, he must read with the blind eye, as the lens used in this way excludes distinct vision from the other as effectually as an opaque screen. Suspicion is less apt to be excited if the trial frames are used with a glass of low power in the other side. This simple test not only establishes the fact of vision, but enables us to determine its degree, and even to measure the accommodation. Three of my patients were detected in this way, in one case, at least, after a careful trial of the prism test had completely failed.

When blindness of both eyes is simulated, we are, of course, deprived of any optical means of detecting it. Etherization, as suggested in an article on malingering by Drs. Mitchell, Morshaw, and Keen (*American Journal of Medical Sciences*, October, '64) might prove successful. They found it so in deafness; and a case of hysterical deaf-dumbness was detected and cured in this way, some years ago, by Dr. Hutchinson, at the Episcopal Hospital.

These cases of hysterical blindness offer a curious and most interesting psychological problem. In some there is evidently a more or less deliberate deception, the result of an insane craving for sympathy or personal importance, or the motiveless freak of a disordered mind. Patients of this class are like the fasting girls who develop a superhuman ingenuity in the effort to make it appear that they live without eating. One of the patients referred to, after obstinately maintaining the deception for two years, abandoned it at once on detection. In the case of others, however, the charge of intentional deception can by no means so easily be maintained. Indeed a careful consideration of their other symptoms, their surroundings and their precious good character is almost enough to acquit them of acting a part. I have sometimes suspected that, though they read well enough unconsciously, they might not be capable of conscious vision with the affected eye; that there might be some mysterious derangement of the process of perception—a kind of negative hallucination, if such an expression could be allowed.

Though it is often a comfort, in doubtful cases, to remember that patients are not always what they seem, we cannot be too careful to avoid classifying a case as "nervous" until every possible organic change has been rigidly excluded, or supposing that we have nearly explained our patient's symptoms where we have called hysterical. It is too often true that, as Charlot says, neuroses bear within them the germs of material lesions, and that a disease, apparently nervous, may at any moment become an organic disease.

The ophthalmic surgeon meets daily with patients whose symptoms not many years ago might well have been classified as hysterical, but when the deeper knowledge gained by the ophthalmoscope and optical tests now proves to have a substantial basis for their complaints. Doubtless, the limits of this convenient term will be still further restricted, in proportion as our knowledge of pathology expands and our means of accurate diagnosis are extended.

The discussion on Dr. Harlan's paper was opened by Dr. Wm. F. Norris, who said he agreed with Dr. Harlan in regard to the importance of hysterical eye symptoms. He thought we should be on our guard in making the diagnosis of hysterical eye affections, particularly as central organic nervous disease was sometimes present without optic atrophy or other ophthalmoscopic appearances.

Dr. Wm. Thompson said he was much interested in Dr. Harlan's paper. He had, however, recently adopted a special method of treating hysterical eye affections. He said he had a case some months ago—a woman, who was blind in her left eye. The eye-ground was normal. She had frequent hysterical attacks. She was deaf in one ear, could not taste or smell, temperature abnormal, skin pallid, and there was loss of sensation in one-half of the body. About that time Burquism or metallo-therapy was brought to his attention. He tried it in this case, and found that iron was the metal to which she responded. He put her on this, and she gradually recovered. Her sight returned. This woman's circulation was poor on the left side. He thought that circulatory disturbances were often at the root of these hysterical conditions, and that the application of appropriate metals had a decided effect in such disturbances.

Dr. Wm. S. Little said, in no class of diseases does the physician feel the necessity of knowing how to handle all the "scopes," in order to exclude or recognize diseased conditions, as in these cases of hysteria. It has been my habit to classify these cases as follows: Cases of hysteria manifested in the eye alone, without any lesion in the eye or elsewhere in the body. Cases of hysterical manifestations in the eye, with lesions elsewhere in the body and none in the eye. The same, with lesions elsewhere and in the eye. Another class of cases with hysterical conditions in other parts of the body, due to ocular conditions. The first class of cases are rare, and a few kind words or a little electricity may suffice for treatment; but in the other cases, to decide on the proper plan of treatment calls for more discrimination, and these cases will go from physician to physician till they may even, as the author of the paper says, fall into the hands of the gentleman who divides the internal rectus.

Dr. Wm. Osler mentioned the case of a girl suffering from hysterical blindness in the London Hospital in 1873. Various tests were employed without success. One of the surgeons suddenly held up before her a large frog, which caused her to scream and roundly abuse the doctor, and immediately cured her of her blindness.

Dr. Charles K. Mills said that the tendency, during the discussion, seemed to be to regard all cases of hysterical blindness as due to unmitigated shamming. While simulation was an element in many cases of true hysteria, and while in what might be termed pseudo-hysteria it was the chief or only element, all cases of hysterical blindness, or of other hysterical sensory disorders, were not to be explained in this way. The activity of the cortical areas concerned with conscious perception was in abeyance in many of these cases. Sudden and unexpected impressions aroused these centres to action, and thus accounted for the sudden cures which were regarded as instances of detection of imposture. Imposture was present sometimes, but not always.

Dr. Louis J. Lautenbach said that in connection with the subject under discussion, he would briefly report the following case: A colored woman, 26 years old, a cook, strong, stout, and apparently healthy, presented herself, with a history of sudden loss of sight two days previously. Vision of her right eye was $\frac{5}{6}$; of left eye, counts fingers at one foot. It improved by glasses. The optic nerves were very slightly pale, the vessels normal. Both eyes were hypermetropic: the right slightly more than 2 D., the left somewhat more than 1 D. The left iris was dilated, not reacting to light. She was placed on iodide of potassium, 3 grs. in compound tincture of gentian, three times a day. On the 20th inst. her vision in the left eye was $\frac{4}{60}$; on the 22d inst., $\frac{5}{6}$; and on the 24th, $\frac{5}{4}$. She was profuse in her expressions of gratitude for, as she considered it, her wonderful recovery.

Dr. S. D. Risley said he felt indebted to Dr. Harlan for calling attention to the hysterical affections of the eye. He thought, however, that in ophthalmic practice it was peculiarly difficult to draw the line between hysterical symptoms and those having a distinct pathological basis or a physiological anomaly to explain them. The intricate anatomy of the eye was such as to render its proper performance of function especially liable to be influenced by many derangements of the general system. The state of health underlying the group of symptoms characterized by the term hysteria was especially prone to effect a disturbance of the visual function. The disturbance, however, differed from the ordinary manifestations of hysteria, in that the symptoms had a demonstrable physical cause, were beyond the control of the patient, and were constant during the existing state of health. Thus the feeble innervation of the hysterical patient was liable to diminish the range of accommodation and power of convergence, rendering the comfortable use of the eyes impossible. Again, the feeble or deranged circulation in the hysterical individual may set up a group of symptoms in the eye, presenting many of the characteristics of serious disease—which, however, are not simulated, but are, in fact, a relative glaucoma. While there is no absolute increase of intraocular tension, the normal tension of the eyeball is sufficient to interrupt the entrance of the feeble blood-stream into the eyes, and thus is set up the same group of symptoms as are present in actual increase of tension, viz., inadequate blood supply to the retina, contracted field of vision, impaired central perception, diminished range of accommodation, inability to use the eyes, particularly at a near point.

Dr. J. T. Eskridge presented a paper on, "A Case of Tumor of the Cerebellum with Monocular Hemianopia."

LEWIS BRINTON, M. D.,
Recorder.

—In a recent board of pharmacy examination, in reply to the question, "What would you do in case a prescription had been wrongly dispensed and the patient's life was endangered?" one reply was, "Go to Canada!"

EDITORIAL DEPARTMENT.

PERISCOPE.

Mental Overwork and Premature Disease Among Public and Professional Men.

Dr. Charles K. Mills, on March 19, 1884, delivered the ninth "Toner Lecture," choosing the above for his subject, of which the following is an abstract:

The longevity of intellectual workers in general is first considered, and is found to be above that of most other classes. The inferences and conclusions of the paper are largely based upon a study of sixty cases, especially collected by the author, cases in which loss of health or life had been mainly attributable to excessive brain work and brain strain.

These cases are arranged into two classes:

1. Men in political and official life, including cabinet officers, senators, representatives, department officials, governors, and candidates for office.

2. Professional men, including physicians, lawyers, clergymen, journalists, scientists, and teachers.

The actual occupations were: Cabinet officer, 1; senators, 8; representatives in Congress, 10; department officials, 5; governors, 2; candidates for important offices, 2; physicians, 6; lawyers, 7; clergymen, 2; journalists, 4; scientists, 6; teachers, 7.

Twenty-eight of the sixty, therefore, were men in political and official life, and eighteen of these were members of Congress.

The average longevity of men in the higher walks of political life in this country is regarded as considerably below the average of those who occupy similar positions in England. Comparing, so far as information was available, the ages at death of United States Congressmen and members of the English Parliament who have died since 1860, the following results were obtained: Fifty-nine United States Senators gave an average of 61 years; one hundred and forty-six United States Representatives, an average of 55 years; the average of both being, therefore, 58 years. One hundred and twenty-one members of Parliament gave the remarkable average age at death of 68 years.

Taking twenty-five of those that might be regarded as the most eminent American statesmen of the last one hundred years, and comparing their ages at death with those of the same number of the most distinguished English statesmen, the United States gave an average of 69 years, and Great Britain of 70—no practical difference. It was noticeable, however, that much of the best work of the great English statesmen—of Palmerston, Derby, and Beaconsfield, for instance—had been done at an advanced age, when most American public men have ceased to do anything important.

The lecturer considers some of the causes which lead to mental overwork and breakdown in American public and professional life, the early warnings of such overwork, and the forms of disease most likely to result.

The preparation, qualifications, and modes of life of American public men are discussed, and in some instances comparisons are made with English statesmen. The histories of many of the cases are briefly sketched. The special conditions which lead to overwork and its consequences among physicians, lawyers, journalists, scientists, and teachers, are presented at some length, with illustrative cases. The evil effects of competitive examinations and cramming, upon both teachers and scholars in our public schools, are also described.

The symptom-groups and diseases represented by the series of sixty cases are summarized as follows: Acute neurasthenia, 18; insanity, 10; phthisis, 9; diabetes, 4; cerebral hemorrhage, 4; Bright's disease, 3; posterior spinal sclerosis, 3; pneumonia, 3; bulbar paralysis, 1; angina pectoris, 1; erysipelas, 1; hepatitis, 1; enteritis, 1; glossitis, 1.

It was found almost impossible to present in orderly array all the symptoms which may be regarded as the indications of nervous exhaustion, and the probable precursors of premature disease from brain-strain and overwork, these symptoms varying somewhat with the individual—with his hereditary tendencies, his habits, and his surroundings. There were, however, certain common and positive evidences of existing or coming evil which were present in many cases.

Neurasthenia and lithæmia are discussed.

The most important conclusions are summarized as follows:

1. Intellectual work does not of itself injure health or shorten life, but mental overwork, particularly when associated with emotional strain, is a frequent cause of nervous break-down and premature disease.

2. The average longevity of men in the higher walks of public life is less in this country than in England. Politics here is not, as there, in the best sense a vocation; and our public men, in many cases, succumb in health, or fail to attain long life, because they go into careers unprepared, by inheritance, education, and training, for the severe demands to be made upon their powers.

3. Health and life are sometimes lost through forgetfulness of the fact that mental strain and overwork are particularly dangerous to those in middle life or advanced in years, who attempt brain-work and responsibilities to which they have not been accustomed. The effects of suddenly-imposed mental strain upon these classes are especially disastrous.

4. If not subjected to unusual mental or physical strain, public and professional men, as well as those in other walks of life, although afflicted with organic diseases, may live in comparative comfort, and able to do a moderate amount of work, for many years.

5. Among special causes of premature disease in public life are onerous and perplexing duties

on Congressional committees, the uncertainties and disappointments attendant upon public positions, the great strain to which candidates are subjected during political campaigns, lack of recreation, and social excesses and abuses at the National Capital.

6. Among physicians, lawyers, and journalists, the performance of brain-work under pressure of time, and under bad hygienic conditions, is a common cause of ill-health. Defective education and pecuniary harassments are also special causes of nervous break-down and premature disease among physicians and lawyers.

7. Comparatively few clergymen succumb completely to mental overwork, although many suffer from a mild but annoying form of neurasthenia.

8. The danger to the scientific worker usually arises from too intense and too prolonged activity of the mind in one direction.

9. The system of severe competitive examinations in vogue in many communities saps the health of both teachers and pupils. In our schools generally educational methods are bad, recreation is too much neglected, and unhealthy emulation too much encouraged. Education is not properly individualized.

10. Chronic neurasthenia is not common among men prominent in public affairs and in the professions. Such men are, however, sometimes the victims of a severe acute nervous prostration, which may result in serious organic disease.

11. Nervous strain is one of the causes of lithæmia, which is of not infrequent occurrence among public and professional men, but lithæmia and neurasthenia are not interchangeable terms.

12. The warnings of mental overwork and overstrain vary with individuals and circumstances; but certain psychical symptoms, and such physical symptoms as immobility of countenance, diminished resisting power, heart failure, sleeplessness, cervico-occipital pain or distress, and dyspepsia, are of most frequent occurrence.

13. Insanity, particularly in the forms of melancholia and paretic dementia, is sometimes developed by brain-strain and overwork. A family history of insanity is often present in such cases.

14. Phthisis, diabetes, and Bright's disease, are among other diseases most likely to be developed by mental overwork. Men in whose families phthisis is hereditary, should carefully guard against such overwork.

15. Overtaxing the mind and nervous system may be the exciting cause of almost any serious disorder to which chance, accident, imprudence, or infection exposes the individual.

16. Many diseases, not nervous in their seat or manifestation, are developed directly or indirectly as the result of mental and nervous strain, through exhaustion, impairment, or lesion of the centres of the organic functions.

Two Cases of Phlegmonous Pharyngitis.

The *Med. Press* tells us that Drs. Carrington and W. Hale White brought these cases before the Clinical Society in the belief that they belonged to a class which hitherto had escaped recognition. Patients were seized with intense dyspnœa, and tracheotomy might or might not be performed. The operation, however, appears to be entirely useless, the general, and not the local condition appearing to lead to the fatal issue. The first case was a man, æt. 46, who was admitted into Guy's Hospital in the early morning. He had been ill for seven days, somewhat remittently, some days being in bed, on others at work. He was admitted with laryngeal stertor, but no marked dyspnœa. He was placed in a tent with the steam spray and watched, but in the course of a few hours he died quite suddenly, before the house surgeon could be summoned. At the autopsy, all the soft tissues of the pharynx were œdematous, and on the right side, from the tonsil downwards for two inches, the mucous membrane was minutely injected and swollen with purulent œdema; yellow spots of pus pointed here and there. The same condition spread into the tissue of the epiglottis. On the left side the œdema was serous only. There was very little narrowing of the rima glottidis. With the exception of sub-pleural ecchymoses, there were no other noteworthy points discovered. The second case was that of a medical man, æt. 49, who was admitted into Guy's Hospital on November 10, 1884. He was suffering from dyspnœa, apparently of moderate intensity, but he himself came up to the Hospital for the purpose of having tracheotomy performed. He walked up to the ward. He was placed in a tent with a steam-spray apparatus. It was decided, after consultation with Mr. Clement Lucas, to perform tracheotomy three hours after admission. Just as he was about to be removed to the table, he was seized with spasm of the glottis, and the operation had to be performed in the bed. Artificial respiration had to be resorted to, and was so far successful that he began to breathe spontaneously. He was then seized with an epileptiform convulsion, and ceased to breathe again. Electricity, subcutaneous injection of brandy, and other means were resorted to, and he again began to breathe feebly. He revived so far as to take a draught of milk. All seemed well, and arrangements were made for having him under supervision, when he again ceased to breathe. Efforts were maintained to bring him round for a full hour, but unfortunately were not successful.

Mr. Cripps described the case of a girl admitted to St. Bartholomew's Hospital for gonorrhœa, who, after recovering from this disease, was one evening attacked with sore throat, succeeded by swollen face on the following day, which swelling extended to the opposite side, giving to the face a most peculiar and characteristic appearance. Dyspnœa set in, and quickly increased in severity. Anæsthesia was induced, when respiration almost immediately ceased, and tracheotomy being at once performed, artificial respiration was maintained, but unavailingly. Post mortem, no pus could be found, but the cellular tissue of the neck and pharynx was infiltrated with serum, of which a large quantity drained also from the incision made for tracheotomy during the attempts to set up respiration. Mr. Cripps considered the danger of spasmodic dyspnœa in such cases should preclude anæsthesia, and lead to the practice of making free incisions in the neck, and scarification of the interior.

Mr. Howard Marsh was impressed by the importance of such cases, which, though little rec-

ognized, had, he thought, been described by Sir George Porter, of Dublin, under the name of "acute cellulitis of the neck." He could recall three cases at St. Bartholomew's, not including the one mentioned by Mr. Cripps. One of these, treated by incisions, etc., was attended by sloughing and very fœtid discharge, and terminated fatally. The others were similar in character.

Dr. Goodhart thought the cases quoted by Mr. Marsh were not quite the same as those described in the paper. In the latter there was no diffuse swelling of the neck, nor was there at any time a great degree of severe dyspnœa. The condition of the pharynx was very peculiar; it was brawny, thickened, and the seat of commencing suppuration. The urine was albuminous. The interest of the cases lay in the consideration of their exact relations with diphtheria.

Specimen of Stomach from Case of Poisoning by "Rough on Rats."

To a recent meeting of the Philadelphia County Medical Society, Dr. Willard presented, for Dr. F. W. Coover, of Harrisburg, Pa., a specimen, with the following history: The individual from whom the specimen was taken, was last seen in health between one and two o'clock, Saturday morning, May 3, 1883. About seven o'clock a. m., she was found in an unconscious condition, with two gas-burners in the room unlighted and turned on. On the floor and sofa beside her was some material that had evidently been thrown off from the stomach. I saw her at seven and a half o'clock. She had been carried to her room, and was lying on her back in bed, her body extended full length. She was unconscious, and could not be roused. She threw her hands around, and pressed them over the abdomen. There was no spasmodic rigidity of the upper or lower extremities; she made no resistance when firm pressure was made over the stomach. Extreme pallor of face and upper lip. Mucous membrane of lower lip red and angry-looking. Pupils widely dilated, and not responsive to light. Eyeballs slightly congested. Feeble pulse—about eighty per minute. Respirations increased to thirty per minute. An involuntary discharge from the bowels had occurred. An emetic of sulphate of zinc was administered by the mouth, with but little difficulty, which was followed in a few minutes by free vomiting of a pint or more of slightly yellow-colored liquid, mixed with ropy mucus. The white of eggs, milk and whisky, was given soon afterwards, and retained. After the emetic had operated, there was no retching or vomiting. About noon, some movements were noticed that indicated returning consciousness, but her symptoms showed increasing heart-failure. She would roll from side to side, and restlessness increased. She would slide down in bed. She had more discharges from the bowels, but no urine was voided. By two o'clock, she became conscious, and answered all questions intelligently. She told me she had taken a teaspoonful of "Rough on Rats," dissolved in tea, shortly after midnight; that soon after taking it, she vomited, and from that time she had no recollection of what had since occurred. She complained of no pain, except dryness of the throat, which annoyed her greatly. She felt weak and sleepy, but wanted to get well, and took what was given her cheerfully. The stupor, however, increased, and she died comatose, without any convulsions or struggling, about fifteen hours after having taken the fatal dose. The post-mortem was made about fourteen hours after death. The body was that of a well-developed female, about twenty-three years old, weighing one hundred and forty pounds; *rigor mortis* well marked; all organs, thoracic and abdominal, healthy. Stomach removed, and contained about a pint of liquid, which appeared to be milk, eggs and whisky. The mucous membrane of the stomach was highly inflamed, particularly around the cardiac orifice, portions of it seeming to be detached. The small intestines were distended with gas, the mucous membrane having more than its usual color. The colon and rectum were collapsed and empty. The bladder likewise was empty.

Lead Poisoning of Obscure Origin.

Dr. Roberts Bartholow thus writes in the *College and Clinical Record*, February 1, 1885:

This woman, who has been living quietly in her own house, carrying on her ordinary domestic duties, noticed that the power of her hands was gradually failing. This continued, until now she has characteristic wrist-drop. There is no apparent cause, however, why she should suffer from lead palsy. That the wrist-drop is due to lead, is evident from the symptoms and from the presence of a well-marked blue line along the margin of the teeth in both the upper and the lower jaws. There have also been some disorders of digestion, as nausea, vomiting, and constipation. Lately, some loss of power in the lower extremities has been noted, showing that she is pretty thoroughly saturated with the poison. The urine has not yet been examined, but this will not be neglected; for if the diagnosis be correct, and there can be scarcely a doubt of its accuracy, lead will be found in the urine.

We have carefully investigated every point of which we can think in this woman's household arrangements, and we find no cause for the poisoning. One fact which is mentioned is, however, significant. Her husband is a baker, and over the furnace is a boiler filled with distilled water. The water from this boiler passes through a lead pipe, about fifteen feet long, and is used in the making of bread and in various ways about the house. It is well understood that the action of distilled water on lead pipe is peculiarly dangerous. The water of the city makes an insoluble coating on the interior of the lead pipe, which protects it from invasion. When lead is immersed in distilled water, the presence of lead dissolved in the water can be detected in a few minutes. This is a possible explanation of the poisoning in this case. We shall have the premises carefully examined.

The first thing to be done in the way of treatment is to shut off the supply of lead, and the second is to secure elimination of that which is present in the system. This is best accomplished by the use of the iodides and bromides, preferably the former. I shall avoid the iodide of potassium, on account of the action of potassium, and give the iodide of sodium. In order to reach de-

posits of metals in the tissues, it is essential to give massive doses of the iodide. Twenty grains, well diluted with water, three or four times a day, on an empty stomach, is the proper dose. Purgatives and diuretics are also to be exhibited. To act on the bowels, there is nothing better than Epsom salts, which, while being a laxative, will combine with any lead in the alimentary canal, and form the insoluble sulphate of lead. To increase the action of the kidneys, the patient will be ordered to drink freely of bitartrate of potassium lemonade.

Bullet Wound of the Lung.

Dr. C. B. Maitland thus writes in the *Lancet*, February 14, 1885:

At the present time, when pulmonary surgery is attracting a good deal of attention, the following case may be interesting, showing how comparatively slight the constitutional disturbance may be, consequent on a severe injury to the lung.

On September 7, 1884, Heera, a low caste Hindoo, in the habit of eating and drinking anything he could get, was admitted into the Staff Hospital, Deesa, with a recent rifle-shot wound of the chest. The rifle, a Snider, had been fired 150 yards to his front. The entrance was between the second and third ribs, two inches from the right edge of the sternum; the ribs were uninjured. There was no exit wound, but the fourth and fifth ribs on the same side were broken midway between the scapula and the spine, apparently a piece of each rib being knocked out. There was considerable shock, but scarcely any bleeding, so a little rum was administered. For ten days the man remained fairly comfortable, the tongue, at first furred, cleaning, and only occasionally coughing up a little rusty sputum. On the twelfth day his temperature was 99.5°, and on examination behind I found a swelling, fluctuating with the respiration, opposite the sixth interspace, in the same vertical line as the break in the ribs. On opening this, a somewhat flattened Snider bullet was extracted—it was lying outside the chest cavity—and about a pint and a half of offensive blood-stained pus let out. For three weeks the lung cavity was washed with carbolic solution (1 in 40), the fluid latterly returning nearly clear. The patient all this time suffered from no inconvenience, except when being injected the syringe hurt the broken ends of the ribs. Air passed freely through the posterior wound when uncovered, and once a slough two inches long came away. The morning temperature was always normal, the evening temperature ranging from 99° to 99.5°; respiration averaged 40, and pulse 96. On October 11 his temperature went up to 100°; so a drainage-tube was inserted in the sixth interspace, without making a fresh wound, and some offensive pus let out. Next morning the temperature and pulse were normal, and the respiration 32. In a week the injected fluid returned clear, and in a month the tube was finally removed. Now, December 17, the man is apparently in perfect health, fatter than before the injury, and the lung performing its functions. His recovery will seem the more remarkable to those acquainted with the prematurely aged and shrivelled appearance of indigent Hindoos.

Catarrhal Pneumonia with Diphtheria.

Before the New York Pathological Society (December 24, 1884), Dr. Van Santvoord presented specimens with the following history: The patient was a child, aged thirteen months, an inmate of Randall's Island Infant Asylum. It had been ailing for about one month, with diarrhœa occasionally succeeding a somewhat constipated condition, and the occurrence of bronchitis some time ago. Prior to the fatal illness there had been no examination of the lungs for several days. On Tuesday night the house physician was called to see the child, when the nurse told him that it had been ailing more than usual for a number of hours. He found that breathing was labored, and on examining the throat discovered a patch of false membrane upon the right tonsil. The child rapidly sank, and died within a few hours. Death occurred within twenty-four hours from the inception of the throat trouble.

At the autopsy the brain presented no very obvious lesion. A patch of pseudo-membrane was found upon the right tonsil, and the epiglottis and the trachea, to about its middle, were coated with false membrane, which, as usual, was somewhat adherent over the laryngeal surface and tonsil, but loosely attached in the trachea. The trachea and large bronchi were injected and coated with copious secretion of muco-pus. About one-third of the lower lobes of both lungs, and about one-half of the upper lobes were hepatized from catarrhal pneumonia. The heart presented no marked lesion, simply a post-mortem clot in both ventricles. The abdominal viscera were normal, with the exception that the solitary follicles were somewhat enlarged throughout the small and large intestines. From about eighteen inches above the ileo-cæcal valve to within two feet of the stomach there were six intussusceptions, but these were so frequently found at autopsies in children that they were regarded as having no special pathological significance.

Puerperal Eclampsia.

Dr. H. D. Fry thus recapitulates a paper on the subject in the *American Journal of Obstetrics*, January, 1885:

1. Puerperal albuminuria is the symptom of a pathological change, or of pathological changes, indicative of a predisposition to eclampsia.

2. The prophylactic treatment of eclampsia, therefore, includes measures adopted to prevent the occurrence of albuminuria.

These are, to improve the condition of the blood by the administration of tonics, iron, and a liberal dietary; and to relieve the renal congestion by attention to the functions of the skin, and by prohibiting the wearing of tight clothing.

3. The urine of all pregnant women should be examined for albumen after the fifth month of gestation, and earlier if any suspicions are entertained of renal complication.

4. With the recognition of the disease, treatment should be directed to its relief. This is divided into general, dietetic, and medicinal.

5. Obstetrical, to which are referred the graver cases of the affection. These, not having yielded to treatment, demand, by the urgency of their symptoms, prompt operative interference.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Quarterly Compendium of Med. Science, -	**2.50**
Reporter and Compendium. - - - -	**6.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**7.00**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE
QUARTERLY COMPENDIUM
OF
MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the *QUARTERLY COMPENDIUM,* which we publish.

It is, in fact, a supplement to the *REPORTER,* being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the *REPORTER* for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address
DR. D. G. BRINTON,
115 South Seventh Street,
PHILADELPHIA.

DEGENERATION AMONG THE RESIDENTS OF LARGE CITIES.

Sanitarians will always teach that a life in the country, intelligently and properly carried out, is much more conducive to health, happiness (because it gives health to a great extent), and to longevity, than is a residence in a large city. The reasons for this are obvious. In the country are to be found all the elements of health, which, if intelligently and properly used, must necessarily redound to the physical, moral, and mental welfare of humanity. In large cities, on the other hand, the natural conditions of our surroundings are artificial (if we may be pardoned the Hibernianism), and it is only by constantly avoiding that which we are constantly tempted to do that we can escape the pitfalls which civilized life (so-called) in large cities has prepared for us at every point.

The very nature of a city life, that is to say, in a large city, is demoralizing to health, and the constant temptation to do that which is prejudicial to our physical welfare is very great.

When Rome became a great empire and the "*Mistress of the World,*" with her cities of unparalleled size, she, of course, had to encounter these temptations, and by them she was defeated.

When Maria Theresa sent her beautiful young daughter from Austria to mate with the young king of the then greatest country of the world, fresh from, and flushed with, the victories of the "little corporal," she was sending her to the mercies and vengeance of those who had been crowded into the "Queen City of the World," those who, leading artificial lives, had looked for something more than nature would give them, and who, ruled by those who were not content with nature, were unfit to govern natural beings.

So commenced the downfall of France; so occurred the downfall of Rome; so is now commencing the downfall of England. In the *Luncet*, Feb'y 7, 1885, we read as follows:

"The lecture delivered last week by Mr. James Cantlie on "Degeneration amongst Londoners," was received with approval not unqualified by dissent. The address, while true to the concentrated life of many large towns besides London

in its general tenor, might be said to be a diagrammatic, or rather a scenic, portrayal of that life. Some of its statements could hardly be received without a qualifying grain, as that, for instance, which declared a pure Londoner of the fourth generation to be impossible. It dealt principally, moreover, with the poorest class of town-dwellers, among whom the struggle for existence is seen in its rudest and acutest phase. This fact, no doubt, has served to heighten the color of the picture. At the same time, it must be admitted that the variation is rather one of shade than of contour, and arises not unnaturally from the necessities of illustration which belong to the subject in question. He who would find the centres of decay in a nation still on the whole robust and active, must seek for them at the points of social tension. The proofs of pressure, starvation, and atrophy, of vice and of brutal reversion, and of their results are all to be found here. The beginnings of the same process may be watched and often remedied in other grades; in this class, one frequently sees the beginning run on to its end in a single generation. Mr. Cantlie is not disposed to let this happen. He does not speak as a mere melancholic or idle image-breaker, but as a practical healer of abuses. His means of cure are two: fresh air and exercise. With regard to the vital importance of each of these to all normally formed persons there can be no question. The existence of various well-known societies and committees for the direct promotion of wholesome living is evidence enough to this effect. The subject for consideration rather is, how to bring these necessary luxuries —for so they must now be described—within reach of the many who have them not; and for the solution of this problem no answer which is not practical is worth having. Any such answer must of course affect the working of our whole civic system. Work, means, and food, the regulation of working time so as to allow of a fair measure of personal leisure and of sleep, are equally matters of the first significance, and may be said to form in many cases the standing ground required for the operation of all other remedial measures. We have good hope that the national mind, recognizing that there is degeneration and that it is curable, will continue to treat it with sympathy, as it has begun to do, and will direct upon it the fresh air of public discussion and the healthy exercise of a wisely corrective legislation."

These remarks are worthy of the gravest consideration. Rome was *Rome;* Paris was *France;* and London *is* England; just as our large cities *are* the *United States.* Among our wealthier classes, the growing tendency is towards a residence in the country; among the medium and poorer classes, the tide of emigration sets towards the large cities; *centralization* is the social as well as the business order of the day, and the people answer to this order. Let us think; let us reflect on the past history of the world; let us remember that physical and mental greatness must go hand-in-hand; let us remember that when Greece ruled the æsthetic world, she also owned the physical world; let us seriously ponder over this, and ask ourselves whether we do right to encourage centralization. The necessities of business (as conducted to-day) call for it; but will it conduce to our political welfare?

Notes and Comments.

The Treatment of Mastitis by Bandaging and Rest.

Dr. Philander A. Harris thus concludes a paper on this subject in the *Amer. Journal of Obstetrics* for February, 1885:

"From my experience in the management of the puerperal and nursing breast, I would form the following conclusions:

"1. That the breasts soon after delivery are strongly disposed to secrete milk, and will usually continue to do so for a few days, even if they be not nursed. If no attempt be then made to nurse or withdraw the milk, the secretion rapidly diminishes, and they return to their normal size and condition of inactivity.

"2. That, as a rule (to which there are probably few, if any, exceptions), the retained secretion does not undergo changes which convert it into an irritant fluid, but instead, it remains innocuous to the walls of the ducts and acini which contain it, and under favorable conditions is finally absorbed without trouble or embarrassment to either the normal or inflamed adjacent tissues.

"3. That, as a rule, the secretion of milk continues only while the natural stimulus, as nursing or other means of emptying the breast, continues to be employed. That the secretion, either in the normal or inflammatory condition, begins to abate when such stimulus is withdrawn, and will entirely cease after a week or two.

"4. That an abundant secretion of milk which has recently and entirely ceased as the result of a comp'ete withdrawal of stimulus, may be again recalled upon the reapplication of the child.

"5. That the presence of a decided inflammatory movement in the breast greatly diminishes secretion in the gland.

"6. That the sympathetic relation between the two breasts is almost, if not wholly, a sensory one. That neither the function of secretion nor the condition of the circulation in one breast is appreciably and directly affected by either physiological or pathological processes which may be going on in the other.

"Inflammation of the breast should be regarded as a progressive rather than a self-limited disease. It is attended by a train of pathological changes which become more severe and complicated until the conditions or circumstances which have produced them and which favor their continuance are removed.

"The inflamed breast should be supported in a well-applied bandage, and no attempt made to nurse or withdraw the secretion until the entire subsidence of the inflammatory movement.

"Sore and fissured nipples often produce inflammation of the breast. If, therefore, in any particular case we have reason to believe that the lesion will soon lead to the development of mastitis, or should it appear that a cure cannot be effected during the continuance of nursing, we shall be justified in the entire suspension of suckling through the affected part until a cure of the local trouble is established.

"The well-applied bandage exerts a salutary influence on the morbid conditions which affect the nursing breast, and it is also the most grateful measure of treatment."

A New So-called Specific Treatment for Typhoid Fever.

Dr. J. W. Hawkins thus writes to the *Kansas City Medical Record*, Feb'y, 1885: "It is said by medical writers of the present day that there is no known specific treatment for typhoid fever. We are gravely told that "the abortive plan by the use of calomel is the only treatment that can be considered ætiological or causal." To this statement I respectfully demur. If calomel aborts the fever in fifteen to twenty days, the bromide-of-potassium treatment will do it in seven to ten days. The bromide of potassium is a medicine (unlike calomel) attended by no bad results, and upon it we can confidently rely. It may be given in any and all stages of the fever—first, second, third, fourth, fifth, or sixth week. If you see the patient on the first or last day of the fever, begin at once to administer the antidote—bromide of potassium. In the whole metasyncritic cycle of remedies for typhoid fever the bromide of potassium stands at the head. It accomplishes what no other known remedy has done, when properly administered. It usually arrests the fever in from seven to ten days after beginning its use. If the treatment is commenced at the beginning of the attack, five-grain doses administered every three hours during the day only, and repeated daily, will usually be sufficient. But if in the last stage, from fifteen to forty grains will sometimes be required. In the last stage of a very severe case, when death seemed almost inevitable, I gave more than two hundred grains in twenty-four hours, producing no gastric disturbance whatever. The patient recovered. Hence from this and other like cases I am led to believe that we have a specific for enteric fever.

The truth of this has since been verified in the treatment of ten additional cases, the fever in every case being arrested in from seven to ten days. I think I am not talking too forcibly when I say that bromide of potassium is as much a specific for typhoid fever as the sulphate quinia is for (ague) intermittent fever.

Attempted Suicide.

The following case, which Dr. Levi Clease reports in the *Louisville Med. News*, is worthy of note:

"May 30, 1879, Joseph Gaume, a barber, while assisting in preparing for burial the victims of the tornado which had swept over Irving that day, stole an engagement ring from a young lady's finger.

"July 21, 1879, while under the influence of a prolonged bout of hard drinking and of fear of personal injury at the hands of the friends of the aforesaid young lady, he attempted suicide by cutting his throat with a razor. Ten minutes at least must have elapsed before Dr. H. H. Tenney and myself reached the place where he lay wallowing in a pool of gore, and bleeding like a stuck pig. He had made several gashes across his throat, below the cricoid and thyroid cartilages. One of the tracheal cartilages was almost severed, and hung by a filament from the wound. The common carotid artery on the right side was cut half off. With every expiration the blood would fill the yawning wound and bespatter the surgeon.

"Dr. Tenney at last succeeded in introducing his finger under the artery and lifting it up from

the bed, while I tied both the distal and cardiac ends. The radial pulse once more became discernible, and the gash in the throat was sewed up. The next morning the patient, with a large pocket-knife, stabbed himself in the third and fourth left intercostal spaces. He aimed at the heart, but struck too high. The nurse heard the hiss of the escaping air. These wounds were closed by adhesive plaster. The neck wound had to be reclosed by sutures; no extra precautions were taken, and July 30th the patient was discharged. I heard that he committed suicide the year after by throat-cutting."

Cocaine in Minor Surgery.

If current reports are to be credited, there is apparently no limit to the beneficent action of cocaine. In the *Lancet*, January 31, 1885, Dr. J. Herbert Simpson reports the following case:

Miss B——, whose breast I removed for scirrhus in February, 1884, found a week ago that two small nodules of the disease, each about the size of a pea, very hard and painful, had appeared near the cicatrix of the operation wound. The nodules were about three inches apart. On January 23 I injected three minims of a four per cent. solution of the hydrochlorate of cocaine on either side of one nodule; and, finding that after waiting ten minutes there was no pain on pinching the part, I cut down and removed the nodule, having to make an incision an inch and a half long. The patient felt absolutely nothing of the operation until I inserted the sutures, and that, she said, was hardly to be called pain. After closing the wound, I injected another three minims near the second nodule, and operated in the same way; and although a little pain was felt, owing, I believe, to my not having waited sufficiently long for the third injection to take effect, it was very trifling; and from beginning to end, this operation under cocaine was a decided success. There were no after-effects from the drug, and both wounds are healing by first intention.

How Syphilis may be Contracted.

The following case, which Dr. Amos Carter reports in the *Indiana Medical Journal*, is worthy of note, as it carries with it a very wise suggestion to prison authorities. To give his own words, the doctor says:

"I have had a case of syphilis that is of interest only from the manner in which it was contracted and the location of the chancre. The patient was a boy aged 15 years. He was admitted to the Indiana Reform School for boys, October 21, 1884. About the first of November he complained of soreness in the anal region, and examination revealed a chancre about one-half inch from the opening of the anus. He said that he had been confined in jail with a 'man who was in for attempted rape,' and who had syphilis; that it was contracted 'by using the same closet the man did.' By close inquiring, the boy acknowledged that the demon with whom he was confined had induced him to consent to sodomy. This revealed the means and source of contagion.

"The case got along reasonably well; the rectal wall was somewhat thickened, but he will make a very good recovery.

"Such occurrences as this being possible, our county jails ought to be so arranged as to keep boys separated from older and more hardened criminals."

Inoculation from Malignant Pustule.

From the Paris correspondence of a foreign exchange we note that a patient was lately admitted into the Lariboisière Hospital with a malignant pustule above the eyebrow. He was employed in the slaughter-houses of La Villette, and killed and prepared for sale sheep imported from the south of Russia. The malignant character of the pustule was evidenced by intense fever, 107° Fahr.; pulse 120, and considerable œdema. The subparotid glands were much swollen. Two days before the patient was admitted into the hospital, he complained of itching of the forearm and back of the hand. The œdematous area was cauterized, and the scars were removed until the tissues bled. The patient's condition improved from day to day, until all danger disappeared. Nevertheless, the glands continued hard and swollen. M. Proust, who treated the case, wished to ascertain if the blood was infected when the patient was admitted. Artificial cultivations from the blood on broth were made, but were sterile. A drop of the purulent serum taken from the pustule rendered the broth fertile, and bacteria appeared in it. Guinea-pigs inoculated from this cultivation died from charbon.

Malformation of the Female Sexual Organs.

Dr. B. Bernard Browne thus concludes a paper on this subject in the *Jour. Am. Med. Ass.*, November 8, 1884:

1. Nearly all the malformations of the female sexual organs, previous to puberty, result from arrest of development.

2. As the upper and lower portions of Müller's

ducts develop independently of each other, we may find the ovaries developed without the uterus, and *vice versa*.

3. Perfect development of the external genital organs and the mammary glands does not preclude defective development of the vagina, uterus or ovaries.

4. Entire absence of the uterus or the ovaries can only be determined by post-mortem examination or by laparotomy.

5. A patulous urethra is not the result of sexual intercourse through this organ, but is caused by arrest of development.

6. In congenital atresia of the vagina, a patulous urethra is the rule; in acquired atresia, it is the exception.

Cocaine in Chordee.

After a while we will hear about "*Cocaine in Cancer;*" but, as universal as would seem to be its therapeutic application, if all reports are to be credited, yet it is our duty to give publicity to all reports of its use that bear some evidence of authority. An anonymous writer thus discourses in the *New England Med. Mo.*, February 15, 1885:

"I have had two cases recently of chordee, accompanying gonorrhœa, which have yielded easily to the soothing influence of an injection of hydrochlorate of cocaine. In the first case I had exhausted almost everything in my efforts to relieve. It was one of those obstinate cases with which we meet sometimes, and which seem to defy all treatment. I gave this man an injection of 10 drops of a four per cent. solution, mixed with 30 drops of water. After this injection was introduced, I worked it along the urethral canal until the mucous surfaces were bathed in the solution. I then allowed it to remain several minutes. From this time out, I had no further trouble with either the chordee or the patient. The second case yielded a like result."

The Treatment of Acute Dysentery.

The *College and Clinical Record*, Feb'y 1, 1885, says regarding acute dysentery, Prof. DaCosta says, the best treatment is ipecac., not to exceed gr. xx every two or three hours, guarded with opium, and he has very remarkable results from this plan. It is especially good in puerperal dysentery, as Prof. Bartholow has pointed out. The opium plan (gr. ss every two hours) is good. Next is Rochelle salts, one ounce in divided doses in the first twenty-four hours, and less thereafter. This does not preclude the simultaneous use of small doses of opium. Both the ipecac. and the saline purgative plans should be abandoned in two days if no change in the condition of the patient is seen; they are rapid or valueless in their action. Next comes bismuth subnitrate, gr. x–xx every two or three hours. The use of ice water injections three or four times a day was originated by him some years ago; they are very valuable. Sinapisms are useless and blisters harmful.

Headaches.

Our readers will remember that some time since we published a paper suggesting, and giving good reasons for so doing, that "*Sick Headache*" (so-called) was really due to an affection of the eyes. It called forth much discussion at the time, but comparatively little interest was manifested in the subject. We are now glad to note that Dr. T. Lauder Brunton, in his lectures on "Disorders of Digestion," (*London Med. Times*, January 24, 1885), said that there "was only one so-called minor ailment connected with digestion requiring mention, viz., headache. Headaches were usually dependent either upon the presence of decayed teeth, or of some irregularity in the eyes, more especially in the quality of focal lengths between the two eyes, or astigmatism.

"As persons who were subject to headaches in their youth grew older, bilious headache was very apt to be replaced by giddiness; and this change occurred about the time when the eyes were beginning to get a little presbyopic, and the person began to find the need of spectacles for reading."

Glycerine for Dryness of Tongue and Thirst in Febrile States.

From a foreign exchange we learn that Surgeon Major S. K. Cotter, in a recent number of the *Indian Medical Gazette*, relates the case of a patient suffering from enteric fever who was awakened every ten minutes by the dryness of his tongue, which was parched and covered with sordes. The tongue was painted with glycerine frequently, and the result was that at the first trial the patient slept almost comfortably, waking up about every two hours with the tongue feeling dry, but not really dry to the touch; after renewed application of the glycerine he at once slept again. In six other cases it has been tried and found satisfactory. Surgeon Major Cotter does not attempt to decide whether it acts by increasing secretion from the mucous membrane, dissolving the sordes, or making an artificial coat-

ing. But, in whatever way it acts, its benefit is vouched for when the tongue is parched during any disease.

Drunkenness Treated by Bleeding.

Dr. Cranny reports the following case in the *Med. Press*, February 18, 1885:

T. T., a middle-aged man, who had been employed in a spirit-cellar, where he obtained and drank a large quantity of whisky, was brought to the hospital in a dying state from the effects. The breathing was stertorous and labored, the face swollen and livid, and the pulse intermittent (with each gasp would give a couple of beats and then a long intermission), and pupils insensible to light. With the stomach-pump a large quantity of spirits was removed, sinapisms put on his legs and neck, and strong coffee injected into the stomach; but as he gradually became worse, and finding that life was ebbing away, Dr. Cranny opened the median cephalic vein. Immediately after the blood commenced to flow, the respirations became easier and the heart's action steadier, and as soon as about ten ounces had been taken, consciousness returned. He left the hospital perfectly well.

Grindelia Robusta in Cough.

Dr. John F. McCann writes to the *Med. Age*, that such has been his experience with grindelia robusta that he has come to include it in all his cough mixtures, when the seat of the irritation is the middle or upper portions of the air passages. In asthmatic cases its action is simply perfect, and its influence over the condition which he thinks obtains in asthma, was beautifully illustrated in a case which had its origin in strychnia, administered in medicinal doses. The patient, according to his theory, had a tendency to asthma, which the strychnia stimulated into activity. The grindelia afforded almost immediate relief from the attacks, although he is not aware that there is any physiological antagonism between the two drugs. It is its property of relieving the irritability of the bronchi which, doubtless, makes grindelia robusta the valuable drug that it is in coughs.

Hysterectomy.

The French correspondent of the *Med. Press* (February 18, 1885), notes that M. Terrier brought under the notice of his colleagues two cases of hysterectomy (vaginal), one of which was for cancer of the neck of the uterus, and did very well. M. Desprès pronounced himself skeptical as to the alleged nature of the tumor, and he could not understand how the totality of the organ could be removed *per vaginam*. M. Berger said that abroad surgeons have commenced to look with distrust on total ablation of womb for cancer, for the affected glands are more difficult to seize and extirpate in this region than in the axilla. M. Polaillon considered that it was not at all necessary to have recourse to an operation so grave, as cancer was generally limited to the os. In reply, M. Terrier, although admitting the justice of some of the remarks, thought that the operation might be legitimately tried, on account of the extreme gravity of the affection.

A Diuretic Mixture.

Dr. A. L. Hodgden writes to the *Maryland Med. Jour.*, February 28, 1885, that he has found the following combination:

℞. Extr. apocynum cannabinum, fluid, ʒj.
Extr. belladonnæ, fluid, ♏xij.
M.

valuable as a diuretic given in the dose of six drops every hour until effect is produced, or eight doses have been taken, especially in œdema from pregnancy. He has given itas directed above, or in œdema from pregnancy, six drops of the same three times a day for three or four days; some water should be taken with each dose. The belladonna, outside of any other action, seems to be very valuable in checking the secretion of the skin, which materially aids a diuretic action. He has never seen the combination before mentioned in print, nor has he heard of its being used by any person excepting himself.

Sodium Ethylate in Lupus.

From the *London Med. Press*, (Feb'y 18, 1885,) we learn that at a recent meeting of the Medical Society of London, Mr. Startin showed several cases of lupus vulgaris which had been completely cured by the application of sodium ethylate. It will be remembered that Dr. B. W. Richardson drew attention to the value of this substance in the treatment of mucous polypi nasi in an early number of the *Asclepiad*, and it has now been employed with considerable success in a large number of cases of disease. In one of Mr. Startin's cases the lupus growth had involved the alæ of the nose and the adjacent cheeks to a considerable extent. Another case exhibited at the same time was almost entirely cured by erosion and careful scooping out of all the lupus tissue, only two operations having been required to effect the result.

Urban Myopia.

Still daily do we hear of some additional argument against city life. Now, in the *Brit. Med. Jour.* (February 7, 1885), we read that in a recent address at the Society of Arts, Mr. Brudenell Carter drew attention to a form of myopia to which the dwellers in populous places are peculiarly subject, and the *Journal* says:

"There is no doubt that town-life is conducive to short sight. There is not one man in ten who, in walking about a crowded town, does not habitually keep his eyes fixed upon the ground, or, at any rate, upon a very near point. Visual accommodation for near distance becomes habitual, because it is a protective necessity against collisions and other dangers of the streets. Hence dwellers in towns should take frequent walks abroad, so that, by gazing on distant objects, they may preserve their eyes by a healthful relaxation of visual tension."

Amenorrhœa and Gonorrhœa.

In the *College and Clinical Record*, February 1, 1885, we read as follows:

For amenorrhœa dependent upon debility, Prof. Parvin advises the following, speaking very highly of its utility:

℞. Ferri sulphat. exsiccat., gr. j.
Aloës, gr. j.
Olei terebinthinæ, ♏j. M.
Ft. pil.
Sig.—One ter die.

According to Prof. Bartholow, the following, in gonorrhœa, after the acute stage, is efficacious:

℞. Zinci sulphat.,
Plumbi acetat., āā gr. viij.
Ammonii chlorid.,
Aluminis, āā gr. iv.
Aquæ rosæ, f. ℥j. M.
Sig.—As an injection.

Sponge Left in the Abdomen.

A most excellent caution is that taught by the following note from the *Louisville Med. News*:

Dr. C. H. Briddon, at a recent meeting of the New York Surgical Society, the proceedings of which are published in the New York *Medical Journal*, reports a case in which he operated for removal of the uterus by abdominal section. The patient died on the sixth day, and when the post-mortem was made a sponge was found encapsulated with lymph lying in the right iliac fossa.

[At the last meeting of the American Gynecological Society a number of cases of this kind were reported, and they show how careful operators should be to follow the plan of Keith: "Count the sponges before operating, and be sure when you are through that you have them all."]

Muriate of Cocaine in Gout.

Dr. D. D. Davidson, of this city, informs us that he has in a few cases had most satisfactory results from the use of this drug in gout. He uses a two per cent. solution, which is poured into the palm of the hand and then rubbed over the painful part. It only gives temporary relief, but this is a great desideratum and rather unusual, as so far this local anæsthetic has not had the credit of having any effect on the skin. He also tells us that when the pain returned it was less severe. He, too, has found this drug useful in earache.

CORRESPONDENCE.

The Hygiene of the Aged.

EDS. MED. AND SURG. REPORTER:—

Such is the heading of an article in the MEDICAL AND SURGICAL REPORTER of January 24th, by some one reporting "Notes from the Philadelphia Hospital," embodying the utterances of Dr. Horatio C. Wood, Professor of Materia Medica in the University of Pennsylvania. Dr. Wood is high authority with the profession generally as well as with the large class of students to whom he lectures. If there be a responsible position in the world it is that of medical teacher. How fatal is the propagation of error by those who educate pupils to go forth to take charge of the lives of others! Nearly sixty years ago I was deeply impressed by the earnestness and conscientiousness of Professors James, Physic, and Coxe, when lecturing to their classes. No joke ever passed their lips; nothing that had the shade of obscenity in it was ever spoken by them. In the years which have come and gone since that time, it has ofttimes gratified me to listen to some other surgeons and physicians who have filled those chairs with the same high regard for propriety of speech and deportment. In speaking thus, I intend no reflection on Prof. Wood, for I do not know what his habits are. I only refer to the feelings manifested by the gentlemen of whom I have spoken as resulting from their realization of the great responsibility which attached to them as teachers.

Dr. Wood knows full well, that, in the Society of Friends, to which nearly all his relatives belong, and in the principles of which he was carefully reared, abstinence from intoxicating—I ought to say alcoholic—drinks is the rule, and that in that society there is greater longevity in proportion to numbers than in any other society of any kind. The three oldest persons who within the last decade have passed away from the neighborhood in which I reside were members of the Friends' Meeting; one had nearly reached his 97th year, the other two were in their 95th. They were all free from the use of alcohol in any

form. One of them was my eldest brother, who, I can well believe, had not taken during the last seventy years a single teaspoonful of alcohol in any form. A sister, also, reached the age of 85, and was free from its use through all her long life. For 44 years I have wholly abstained, and yet almost measure years with this dear old man —"too good a patient to let die." I wish he had not said *that*. It was too light for the occasion and the presence.

How harmful is such teaching in view of the wretchedness wrought by the use of alcohol in its various forms!

Dr. Wood's class numbers hundreds of young men, and if he should not have urged upon them the use of alcohol on any other occasion for any disease during his lectures this winter, even then he has done them great harm. He has impressed on these young men a belief that alcohol is a nutritive, life-preserving agent, and as conscientious practitioners they will feel bound to advocate its use. They will not wait till people are 75. Even Dr. Wood's rule is "75 or less," and the less has no bounds. Every one who complains of weakness or chronic infirmities will be considered a fit subject for this great health maintainer. To the young doctor of 22 or 25 years, persons of 50 or 60 are quite old, and he will urge on the latter the use of alcohol—the great health preserver—"in some form at meal time." It will not then be taken merely at meals—a good drink of it in some form at bed-time will make him feel good. Many years ago I had a friend who was told that a little brandy after each meal would be useful to relieve his dyspeptic symptoms; he tried it, and boasted to me of its great value. He was, indeed quite triumphant; thought "doctors know but little about dyspepsia." He was just my age. I warned him against it. He has been dead many years. It was a common belief with his neighbors, "that he drank too much." It was evident to all who saw him, and yet he was a vestryman in his church, and had other important reasons for resisting injurious habits.

Dr. Wood speaks truly when he cautions against exposure to high winds—and especially to sudden change, when very warm, to a cold, chilling atmosphere—but it is nearly as applicable to the young and the middle-aged as to the old. Dangerous as such exposure is it is much less dangerous to life than a change from sobriety to the use of alcohol "in some form at meal time." He presents the case of Rev. Dr. Beadle to show the danger of exposure to a chilling wind when the body is warm and not protected by a "buckskin jacket." Dr. Beadle was a noble man, and the mention of his name and death, impels me even at the risk of being called a hobbyist, to turn away from Dr. Wood for a moment, to express my extreme regret that there was not, in the aristocratic quarter in which Dr. Beadle resided, a physician who could have saved him even if he were suffering from a congestion of the lungs. Dr. Beadle's was not an exceptional case —hosts of physicians and other professional men in Philadelphia and in New York have died from congestion of lungs, pneumonia, and pleurisy affections so very amenable to treatment. If, therefore, instead of advising the young men as he did, Dr. Wood had spoken to them of the lamentable fact that the profession in Philadelphia is powerless to relieve a person affected as Dr. Beadle and many other men eminent in the profession have been, he would, by this humiliating confession, have awakened, in their vigorous young minds, a desire to know why these diseases have borne away so many of our medical brethren within the last few years. In their inquiries for the solution of the question they would doubtless have discovered that the use of alcohol "in some form," substituting a more rational treatment had much to do with the loss of so many useful, brilliant men. It is greatly to be regretted that though, since the death of Bishop ——, who came from New York in perfect health, to Philadelphia to perform official duties, and died in three days from congestion of lungs, or pneumonia, and so many other men of high standing in our profession have died from the same affection—as reported by their physicians—that we have never once been informed in relation to the treatment. A few years since a man of about 70 years, sitting on the front seat of his carriage, rode eight miles facing the wind, and though pretty well clad, became somewhat chilled. That night he got pain in his chest and a feeling of oppression. A physician was sent for, and he pronounced his case a congestion of the lungs. At once he set about treating him by giving freely of alcohol in the form of milk punch, and in other forms. This strong man lived but two days, at least less than three. Now, what share of the result belonged to the disease and what to the treatment we can only surmise. How it was in Dr. Beadle's case we know not.

It has often occurred to me that physicians owe much to the soothing influence of the clergy. They never charge us with erroneous practice. However much we may have erred, however disastrous our treatment, when they come to officiate at the closing ceremonies they say, in all sincerity, "The Lord giveth and the Lord taketh away; blessed be the name of the Lord." All of us have had occasion to witness the calming effect of *this* on the family, taking away all blame from us, and placing it, I was going to say, where it belongs—elsewhere. Let us hope that if we cannot be informed of the treatment of Dr. Beadle, that we may be favored by some one with the mode of treatment in the case of the Bishop, or some one of the many others who have fallen by the way before or since the death of Dr. Beadle. We ought to know something of the treatment which prevails in Philadelphia and New York, where alcohol is so great a favorite. Returning from this digression, allow me to present another kind of proof that alcohol is not needed in order that persons may reach advanced age.

To-day the *Friends' Journal* of February 19 (yesterday) came to me, and in looking over the list of deaths—the deaths of Friends gathered from all available sources are published weekly—it occurred to me that it would be fair to take it as an evidence of the truth of what I have said about the longevity of Friends—people who, in advanced age especially, do not use alcohol in any form. In this list of the twenty-four persons whose ages are given, one was in his 94th year, one 90, one 88, one 87, two 84, one 79, one 76,

three 74, one 73, one 71, one 69, one 67, two 65, two 64.

Here we find that of these 24 persons 16 had passed their 63d year. Thirteen had passed 70, 5 from 80 to 90, and one went beyond 90. The combined ages of the 24 amounted to 1,646 years. I had not then thought of comparing this list with the list in the Philadelphia *Ledger*. But on the 21st I sent for that paper and took from it the first 24 notices of deaths, of whom the ages were given ; and here is the record. Only six passed the 61st year—of these six, one was 85, two 75, one 72, one 71. The combined ages of the 24 gave a total of only 916. Taking the next 24 whose ages we published, only six passed the age of 62 ; and of them one was 85, one 82, one 75, two 68, one 65, and one in the 62d year. The ages of the whole 24 footed up only 850 years. These results were so surprising to me that I turned to Friends' Journal again. Not being able to find the one of the previous week, (the 12th), I fell back on the 5th of the present month. In it there were only 23, of the list, whose ages were given. Of these 4 were between 6 and 9 years. Of the remaining 19, twelve were past 72, and of these one was 96, one 92, the others 90, 88, 87, 83, 80, 75, 74, 73, respectively. Their united ages 1,335.

Lest some might think I am prepossessed in favor of Friends, it may be well to say that I never have been a member of that Society, but during my whole life have lived among and mingled with them, and can speak with confidence, of their great temperance. Many of them could have given such testimony in relation to their "clearness" of the use of alcoholic drinks as was given in the recent reply of Dr. Michener. And here it just occurs to me, why should not Dr. Michener, if experience be worth anything, be a better judge of what is proper for old people than Dr. Wood? The former was an *eminent* practitioner before the latter was born. The late Professor Joseph Carson, many years ago, said of Dr. Michener, that "Dr. Ezra Michener was one of the best medical writers with whom he was acquainted." A more earnest, conscientious practitioner, and a more careful observer at the bedside of the sick, would be difficult to find. He has passed through old age. He has practiced his profession for fifteen years since he was seventy-five, and, in these latter years, especially with the aged, and knows full well that alcoholic drinks were not needed for himself, or for the aged people who confided themselves to his skill and knowledge. When he got a severe congestion of the lungs and pneumonia at the age of 87 years he did not resort to the health maintainer, alcohol; but was strong enough to bear the loss of a large amount (℥xv.) of blood, and to convalesce without stimulants. How I wish that some of the eminent men to whom I have referred, Dr. Beadle among the others, could have had the benefit of his great skill and experience.

Dr. Wood has probably not reached his fiftieth year; how comes it then that he knows the conditions of old people? Dr. Michener has gone away beyond his "seventy-five years or less," and knows how strong and healthy a man may be at that age and even much beyond it. Now, in my eighty-first year, even my testimony ought to have some weight—not so much as a professor's, of course, when I say that I go abroad every day, without regard to rain or cold, without fear of congestion of the lungs, that I eat well, sleep well, and use no alcohol in any form.

The belief that alcoholic liquors are never needed for persons in health—and are seldom, if ever, necessary in disease—is not a new one. Numerous medical teachers long since testified against their use. The eloquent and enthusiastic Professor Chapman, of the University of Pennsylvania, affirmed "that the evils of *using* them are so great, that the emptying of Pandora's box was but the type of what had been experienced by the diffusion of these liquors among the human species." I have great respect for Professor Wood, but an abhorrence for all utterances which have a tendency to promote the use of alcoholic drinks in any form. HIRAM CORSON, M. D.

Conshohocken, Pa.

NEWS AND MISCELLANY.

Is Deafness Hereditary?

Dr. R. Mathison, Superintendent of the Ontario Institution for the Deaf and Dumb at Belleville, writes to the Toronto *Mail* a long letter, in the course of which he says: "In Professor Alexander Graham Bell's paper transmitted to the United States Congress upon the formation of a deaf mute variety of the human race, a synopsis of which appeared in your columns a few days ago, he says: 'While we cannot at present arrive at any percentage, it is certain that the proportion of deaf mute offspring born to deaf mutes is many times greater than the proportion born to the people at large.' As far as Ontario is concerned, Mr. Bell is very much astray in his theoretical conclusions. In the Provincial Institution for the Education and Instruction of the Deaf and Dumb, at Belleville, under my charge, there are the histories of 661 mute children, who are now or have been pupils since its establishment. I am acquainted with the parents of about 300 of the children, and have made inquiries during the last five years concerning many of the others. Up to this time I have been unable to find that any of the parents were or are deaf or dumb. A few of the grandparents, however, were mutes. A considerable number of deaf and dumb persons in the province are intermarried and have children, and in every case that has come to my knowledge the children can hear and speak. There may possibly be a few instances of hereditary deafness in the province that have not been reported, but they are so very few in proportion to the number of deaf and dumb persons, and form such a small fraction of the population, that an evolution of a distinct race of mutes need never be feared. Of the 661 above noted, 262 were born deaf, the others lost their hearing by fevers, measles, colds, etc."

A Wonderful Memory.

L. F. Gordon relates the following anecdote (*Druggist's Journal*, February, 1885,) of the late Dr. Addison Alexander, of the Theological Semi-

nary at Princeton, which well illustrates the remarkable power of memory possessed by him:

On one occasion a large class of forty or fifty were to be matriculated in the seminary in the presence of the Faculty. The professors and the new students being all assembled in a large hall, each student in turn presented himself before the professors, had his credentials examined by them, and if the same proved satisfactory, entered his name in full and his residence in the register. When the matriculation was complete and the students had retired, there was some bantering among the professors as to which of them should take the register home and prepare from it an alphabetical roll—a work always considered rather tedious and irksome. After a little hesitation, Dr. Alexander said: "There is no need of taking the register home, I will make the roll for you," and taking a sheet of paper, at once from memory, without referring to the register, and merely from having heard the names as they were recorded, he proceeded to make out the roll, giving the names in full, and giving them in their alphabetical order. This was a prodigious feat of pure memory; for in order to make the alphabetical arrangement in his mind, before committing it to paper, he must have had the entire mass of names present in his mind by a single act of the will.

A Sad Instance of Brutality.

Nurses are only human beings, and are oftentimes very much tried, but we can offer no excuse for the following which is stated by a correspondent of the *British Medical Journal* to have occurred in the hospital at Necker: A patient, aged 48, had been for some months under treatment for a disease of the heart. When in bed he suffered such agonizing pain, that the medical officer ordered that he should sit in a chair instead of going to bed. The male nurse who attended to him wished to force him to leave his chair and go to bed; the sufferer reminded him of the direction given; but the nurse was so persistent, that his victim cried out, "Do you want to kill me? I shall not go to bed." A brutal answer was given, and, with the aid of another nurse, the patient was forced to lie down in his bed. The nurses left the ward, and, two hours later, found him dead in his bed. The nurses notified his death without mentioning any of the circumstances attending it, but the other patients in the ward made them known to the physician when he went his rounds. Both nurses have been arrested, and will be tried for manslaughter.

The Risks of Sword-Swallowing.

This exceedingly dangerous trick, or performance, of jugglers, had recently a most disastrous termination in England. The *London Med. Press*, February 4, 1885, says that there died at the Newington Infirmary a few days ago a man whose trade it was to perform feats of jugglery, among which was included the sword-swallowing trick. He had, two days before admission to the infirmary, attempted to perform the customary trick, when he was attacked with severe pain and vomiting of blood, attended with great difficulty in breathing and swallowing. After being submitted to treatment in the infirmary, no improvement took place in his condition, and he died a few days after the accident. This unfortunate victim to sensationalism adds one more to the long list of those whose end is precipitated by attempts to gratify the public taste for morbid kinds of entertainment; and, preach as we may, it is certain that such exhibitions as sword-swallowing, leaping from great heights into nets, turning somersaults in mid-air, and trapeze exercises under circumstances of imminent danger, will be insisted on by the uneducated thousands who make up the classes on whom music-hall proprietors depend for an income. Nor is it merely the lower orders who supply the audiences ready to applaud each fresh risk incurred by "sensation artistes;" many of their number occupy a much higher rank in social life; but it cannot be concealed that it is the intellectual equality such people exhibit with the half-savage rough of the Casino that is mainly answerable for the unseemly association of the two classes in pursuit of amusement.

The Chloroform Habit.

It seems that one of the curses with which human nature has been afflicted is a desire for some form of intoxicant. In the *Brit. Med. Jour.*, (Feb'y 7, 1885,) we read that inebriety is by no means confined to alcohol. Though in England inebriety from opium and either has attracted comparatively little attention, the habit induced by these and other narcotics has been described by observers in other countries. The latest development of excess comes from the United States, in the shape of a record of several cases of addiction to chloroform. In one instance, the *habitué*, a very abstemious physician so far as alcohol was concerned, accidentally experienced the pleasurable sensations of intoxication from this agent, and gradually lapsed into confirmed nightly inhalation of chloroform, extending over three years. By this time, his regular dose was three drachms. Change of scene and of circumstances caused a break in the habit; but the presence of chloroform brought about a relapse. Shortly afterwards, a struggle for emancipation from the slavery to chloroform was begun, which, after extending over two years, was finally successful.

A Chemical Analysis of Food.

The report of a chemical analysis of pieces of bologna sausage, submitted to him by Health Officer Veale, of this city, has been prepared by Professor Leffmann, and turned over to the department. The report was made with reference to cases of poisoning resulting from the eating of the sausage which it was believed had become so stale as to promote the formation of alkaloids. It says: "Such cases are not uncommon, and, while as yet not clearly elucidated, there seems to be no doubt that in such complex articles of food a decay takes place somewhat different from ordinary putrefaction, during which alkaloids analogous to strychnia and atropia are formed. To these bodies the poison is due. I have examined a number of

specimens of sausage, cream puffs, and roast meat, which had caused marked symptoms of poisoning, in all of which no metallic poison or parasite could be found. I have no doubt that the explanation given above is applicable to the present case."

The analysis was made because of reports of several cases where illness had resulted from eating smoked sausage.

Dr. Klein on the Cholera Bacillus.

During the present excitement over Dr. Koch's reports on the cholera bacillus, it is well, in order that undue enthusiasm may not run away with our judgment, to note that at a recent meeting of the Royal Society of London (*Lancet*, February 7, 1885), Dr. Klein read a paper on the Relation of Bacteria to Asiatic Cholera, and showed clearly that the "comma bacillus" of Koch does not behave differently in cultivation from the similarly-shaped organisms found by Lewis in the mouth, and by Deneke in cheese. On many other points, *e. g.*, as to the presence of the organisms in the intestinal mucosa, the action of acids upon their development, etc., Dr. Klein has arrived at results entirely opposed to those of Koch; and he explains some of these divergences by the difference in time at which the post-mortem examinations have been made. The English Commission made the examinations as early as possible after death, and found that the "comma bacilli" increased in number *pari passu* with the length of time that elapsed between death and the examination.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, for the week ended February 21, 1885.

Battle, K. P., assistant surgeon. To proceed to Pittsburgh, Pa., for temporary duty, February 19, 1885.

RESIGNATION.

Heath, W. H., passed assistant surgeon. Resignation accepted, as tendered, by the Secretary of the Treasury, February 14, 1885.

PROMOTION.

Kalloch, B. C., assistant surgeon. Promoted and appointed passed assistant surgoon by the Secretary of the Treasury from March 1, 1885, February 19, 1885.

Northern Medical Association.

The Northern Medical Association of Philadelphia was organized in 1847; disbanded in 1883; re-organized December 12, 1884. The following are the officers for 1885:

President—Dr. Philip Leidy.
Vice President—Dr. H. C. Paist.
Recording Secretary—Dr. Joseph S. Gibb.
Corresponding Secretary—Dr. J. Henry Smultz.
Treasurer—Dr. John T. Walker.
Censors—Drs. Henry W. Rihl, Silas Updegrove, Robert J. Hess, Charles P. Stout.

Apparent Death.

The *Weekly Medical Review* (February 21, 1885), says that the Paris correspondent of the Jour. Amer. Med. Association narrates an incident of Dr. Canepa, who, in the cholera epidemic at Genoa was supposed to be dead. The preliminary funeral ceremonies were performed, but when the undertaker took the coffin to the door he was met by the "corpse" with the inquiry why he was left so long without his tea and rum. A consultation is said to have resulted in the hypodermic intravenous injection of salt solution. He died, but we trust the consultants did not refuse their confrere the privilege of his own simple remedy.

Items.

—M. Gavoy, of Paris, has invented an instrument for determining the degree of mobility of the brain in the cranium; he has shown it to the different scientific and medical bodies. It is termed a kinesiometer.

—In the *Medical Record* we read that dilute phosphoric acid is a pleasant acid in fevers, and dissolves phosphates in the urine quite as well as the other mineral acids. It is well given in lemonade or syrup of raspberries.

—Dr. Henry T. Helmbold, who has been more widely advertised than any other patent medicine man, proposes, now that he has been released from the Norristown Insane Asylum, to re-establish his business in New York city.

—A correspondent of the *Weekly Drug News* writes of a patient who wanted "some more of them pills, but would like them in some other form, as it was such a trouble to pick the shells off." He had been taking quinine in capsules.

—The *Centralblatt für die Medicinischen Wissenschaften* appears under new editorship. Professor Kronecker has been called to Bern, and Drs. M. Bernhardt and E. Salkowski now edit this journal, assisted by Dr. Senator, whose name still appears on the title-page.

—A new chair of Pharmacology has been established in the University of Königsberg, to which Professor Horst Meyer, of Dorpat, has been appointed. It has been formed by a division of the chair held by Professor Jaffe, who will continue to lecture on Hygiene and Medical Chemistry.

—Talleyrand, the Prime Minister of Napoleon, was disliked by Madame de Stael. It so happened that Talleyrand was lame, and Madame cross-eyed. Meeting one day, Madame said: "Monsieur, how is that poor leg?" Talleyrand quickly replied: "Crooked, as you see."

—In the *Russkaia Meditzina*, No. 36, 1884, p. 740, Dr. Sher, of Proskuroff, Podolsk government, used alum, 8 grains two or three times a day, in 31 soldiers with intermittent fever of fresh standing. In 21 cases cure followed. In the remaining 10 alum failed, and cure was subsequently obtained by quinine.

—To the Carlisle Medical Society (January 8, 1885), Dr. Douie showed an infant with congenital deformities. There was extreme talipes equinovarus on both sides, and also flexion of both wrists, with extension of the first phalanges, and flexion of the second and third phalanges.

—To the New York Obstetrical Society, Dr. Hanks reported, with regard to a case of punc-

ture of the gravid uterus in the performance of ovariotomy, followed by miscarriage after the patient's convalescence and discharge from the hospital, that he had lately delivered the patient of a well-developed child at term.

—The patient's gratitude to his doctor is part of his disease. It is most declared when the fever is highest, cools off during convalescence, and entirely disappears with the complete return of health. The physician who is in the habit of letting his bills run to the end of the year, is furnished with frequent illustrations of this fact.

—Dr. F. Peirce states in the *Brit. Med. Jour.* that he had to open a mammary abscess. The organ was exquisitely painful. He injected twenty minims of a two per cent. solution of hydrochlorate of cocaine. In ten minutes the whole gland was anæsthetic, and he was able to make a free incision without causing any pain.

—Dr. G. L. Magruder, of Washington, D. C., reports in the *Am. Jour. of Obstetrics* successful results from the use of "chloride of gold and sodium" in pertussis. His formula was:

℞. Auri et sodii chlorid., gr. ij.
Aq. destil., ℥j,

with directions to give five drops every two hours, commencing as soon as possible.

—About six thousand persons are believed to have died during the cholera epidemic at Naples, Italy. The notoriously bad hygienic conditions there existing doubtless made the epidemic so fatal. Into many of the streets the sun never enters, so narrow are they, and the buildings so high. Many of the people live in cellars, thousands live huddled together, ten or fifteen in a single room, without distinction of sex, with the most miserable food.

—To cut short the paroxysm in whooping-cough, Prof. DaCosta recommends the inhalation of—

℞. Sodii bromid., gr. xx.
Ext. belladonnæ fluidi, gtt. ij. M.

Sig.—The spray to be inhaled just prior to occurrence of the paroxysm.

In the interval, quinine should be pushed up to the point of tolerance.

—Dr. Mortimer Granville complains that a prescription of his for gout has been wrongly copied from a contemporary into the public journals, drachms being substituted for ounces, and that he has reason to believe that much harm is being occasioned thereby. Dr. Granville rightly observes that such proceeding is irregular, and we should imagine that any journal thus acting was intentionally playing into the hands of quacks.

—Dr. V. Poulain writes to the *Brit. Med. Jour.* that he has always found a tablespoonful of fine bran in bread and milk, night and morning, to be the best method of combating constipation in children, and it is very useful in conveying to the child silica and phosphates. The bran should be allowed to soak in the milk, and then, when warmed up to a little below boiling point, it should be poured on the bread.

—The sewerage scheme of Paris devised by Dumont contemplates the construction of a drain about 100 miles long from the city to a covered reservoir below Herblay, and the establishment of pumping stations at Eragny and Serifontaine. The cost of construction is estimated at $12,000,000. For nine months in the year almost all the sewage will be utilized for the purposes of irrigation; and it is expected that the pumping stations will be fully maintained by the sales of the sewage.

—Unquestionably there is a degree of eager, ceaseless absorption in exciting work, involving immense mental, moral and physical exertion, which is capable of breaking down the strongest and best constitution. But unless my own experience is altogether exceptional, such instances are rare, and the vast majority of cases met with are those in which an amount of work and excitement entirely consistent with the maintenance of good health, if the laws of health were duly observed, is rendered destructive by reckless disregard of these laws.—*Dr. Pepper's Address before the Med. and Chir. Fac. of Med.*, 1884.

—A curious question submitted by the Archbishop of Lyons to the Society of the Holy Inquisition, has just been decided by that body. It was to this effect, "Is craniotomy an operation which could receive the sanction of the church? or in other words, given a woman in child-birth who is found to be unable to bring forth, from causes derived from a peculiarity in her own formation or that of the child, and that it be evident that one life must be sacrificed for the other, which life should be spared?" The Society was unanimous in pronouncing in favor of that of the child.

OBITUARY NOTICE.

ELLERSLIE WALLACE, M. D.

Dr. Ellerslie Wallace, formerly Professor of Obstetrics and Demonstrator of Anatomy at Jefferson Medical College, died at his residence 1130 Spruce street, in this city, March 9. He had been in failing health for two years, but his condition had not been considered at all critical until two weeks ago.

Dr. Wallace was born in Philadelphia, June 15, 1819, and was of Scotch descent. He was educated at Bristol College, and graduated as a civil engineer. Later he began the study of medicine with his brother, Dr. Joshua Wallace, at that time Demonstrator of Anatomy at Jefferson College. In 1843 he received his diploma. A few years later he became resident physician of the Pennsylvania Hospital, and held the position three years. He left the hospital to take the chair of Demonstrator of Anatomy in Jefferson College, where he remained for sixteen years, and only resigned in 1862 to take the higher chair of Obstetrics and Diseases of Women and Children. This latter he resigned two years ago on account of ill health. Dr. Wallace had been elected successor of Professor Gross as dean of the college, and this he also resigned two months before his professorship. He was a prominent and active member of the Philadelphia County Medical Society and the College of Physicians. As a class lecturer he had few equals in the United States. His family consists of a wife and one son. The latter is a graduate of medicine.

ANTISEPTIC SURGERY.

Address Delivered at the Yearly Meeting of the Schuylkill County Medical Society by the Retiring President,

J. C. BIDDLE, M. D.,

Surgeon-in-chief of the State Hospital for Miners in Ashland, Pa.

Mr. President, Members of the Society, Gentlemen: It is the time-honored custom for the retiring president to read an address on a subject connected with medicine. As I have and intend to make surgery a specialty, it becomes me to speak of this noble branch of our science and art. Immense progress has been made in every direction, operations are to-day performed of which our forefathers scarcely dreamed, and human life is now frequently saved, where our ancestors were satisfied with insuring euthanasia to the sufferer. But, if we look at the causes which thus advanced surgery, one factor, the discovery of one man seems especially to have made this progress possible. It is to antiseptic surgery, or Listerism, as it is called after him who first introduded it, we owe most of our advancement. Since its employment, the once dreaded peritoneum has ceased to be feared; the cavity of the knee-joint is no longer the "noli me tangere" (don't touch me), and the mortality rate shows fewer and fewer cases where death sets in from exhausting suppuration.

But if antiseptic surgery can produce such results, why is it, you may justly ask me, that at least in this country it is, comparatively speaking, but rarely employed? First, let me tell you that the same remark concerning England and the continent of Europe cannot be truthfully made. Nearly all of the most celebrated surgeons of our age in Europe practice Listerism, more or less modified; and even in our country certain operations, especially those in which death from prolonged suppuration, pyæmia, or septicæmia is mostly to be feared, are no longer performed without antiseptic precautions.

There are probably three causes which, united, have prevented many American surgeons from adopting Listerism and strictly adhering to the rules of aseptic surgery. First, all those factors which mainly give rise to sepsis are less to be feared in this country than in Europe. The people in general here are better nourished, and we seldom see such degraded, and impoverished, and badly-fed individuals as represent the type of the poorest classes in Europe. With us, as a general rule, people are cleaner, and the miserable and filthy hovels that are too often the abode of the poor laborer in Europe, are here but rarely met with.

A second cause of our neglect of Listerism may be found in the fact that the details of it are but imperfectly known; and the third cause is explained by the difficulty with which all the minutiæ of aseptic surgery are performed. Certain bandages and apparatus essential to the strict execution of real Listerism, have to be manufactured wholesale to be at the disposal of the surgeon. This want, however, has of late been supplied, and most wholesale druggists, or the instrument-makers of our large cities, keep continually on hand all the paraphernalia needed for the faithful compliance with aseptic surgery. The difficulty of its execution only, therefore, remains,

and I hope to convince you that this should be no objection to the adoption of Listerism in hospital as well as in private practice. If a surgeon has practiced strict antiseptic surgery but a few times, he will discover that it is connected with very little trouble; and if you consider that the first antiseptic bandage applied in a case may often be left for weeks undisturbed, you will agree with me that strict Listerism does not increase the labors of the surgeon, but indeed decidedly diminishes them.

As all the necessary appliances can, therefore, be procured, it is easy to become an expert in aseptic surgery, and as it relieves the surgeon from a great deal of superfluous labor, every operation ought to be performed according to the rules of Listerism, and considering the fact that it immensely enhances the chances of recovery in many cases its adoption ought to be obligatory, and the death of any case, if it could have been prevented by perfect asepsis, should be justly ascribed to the criminal negligence of the surgeon.

To do my share in spreading the knowledge of antiseptic surgery, is the object of this paper, and I was determined the more to discuss it as my position as surgeon of the State Hospital for Injured Persons of the Anthracite Coal Region of Pennsylvania, gives me the opportunity of showing to you its practical working.

At the boundary between the animal and vegetable kingdom, there is an immense class of microscopical beings, and to-day it is still doubtful whether they are animals or plants, though the majority of investigators seem to incline to the belief that they belong to the vegetable kingdom. Nevertheless, they are known by the name of animalculæ. They form two large subdivisions: hyphomyceti and schizomyceti. They are distinguished from each other mainly by their mode of propagation, the first so-called fungi or moulds multiplying by the aid of spores, while the second do so by division. The first give rise to diseases of the skin and mucous membrane, as favus, aphthæ, etc., but those of the second class which are pathogenic in their nature, make their ravages within the body.

These last have received the generic term of bacteria, on account of their rod-like shape. Many of these are peculiarly formed, and this difference in their shape has given rise to a classification which divides them into micrococci, having a circular shape; bacilli, short or long rods; bacteria proper, shortest rods; vibriones, wavy shape; spirilli, short stiff screws; and spirochætæ, long flexible screws.

How rapidly they multiply when brought into favorable surroundings, you may judge from the following statement, taken from an article of Prof. Engel's in the Medical and Surgical Reporter. "Of one single bacterium, which during the first hour has divided into two, these during the next in 4, and within 3 hours in 8, after 24 hours have already become $16\frac{1}{2}$ millions, after 2 days $28\frac{1}{2}$ billions, and after 3 days 47 trillions. If in this manner the development could go on unimpeded, the breed of bacteria springing from one germ of about $\frac{1}{500}$ mm. in length and $\frac{1}{1000}$ mm. in thickness, within less than five days would completely fill all the oceans of the earth; and the descendants of one single micrococcus, whose weight is so little that 1600 millions of them weigh but one grain, would within three days reach the enormous weight of 15 millions pounds."

Scientific researches have proven beyond a doubt that certain species of bacteria are the pathogenic element of infectious diseases. While all authors do not agree that the bacteria are the original cause of some of these maladies, the following facts are undisputed. No putrefaction, no decay, would take place after death were it not for septic bacteria. Then, there are many chemical processes which are produced and kept going solely by these microbes. The change of sugar into alcohol and carbonic acid, the so-called alcohol fermentation, is due to the activity of the yeast plant. And when fermented fluids become acid, the change of their alcohol into vinegar is caused by a bacterium. When milk gets sour it is induced by a rod-shaped bacterium, while the green and blue color of pus must be ascribed to another variety, and the discoloration observed on potatoes, cheese, boiled eggs, etc., in moist air is brought about by a micrococcus. It is not my intention to enter into a detailed description of these bacteria, which give rise to acute or chronic infectious diseases, as typhoid fever, etc., but I will at once mention the discovery of the pathogenic elements of that great group of septico-pyæmic diseases. Klebs has proven that micrococci cause the septic cysto-pyelonephritis; Rindfleisch and others have demonstrated and cultured those causing septicæmia and pyæmia; Lucke and Koohn, those inducing osteomyelitis, and Nepven, Oeth, Billroth, etc., those of erysipelas. The cause of septic endo-carditis, so long puzzling physicians, has been shown to be due to micrococci colonies.

These septic bacteria develop only under certain conditions—in the healthy being they cannot propagate. They abide in parts of the organism

which have lost most of their vitality, or have become mortified, and in which these microbes cause putrid decomposition, whose products, if absorbed and carried into the blood act as poisons upon the system.

Possessing the knowledge of these facts, Prof. Lister, in Edinburgh, conceived the happy idea to prevent completely the entrance of septic bacteria into wounds. He correctly reasoned as follows: If no decay, no putrefaction, no formation of pus, no septic process of whatever kind, can take place in a wound without the presence of bacteria, all that is necessary to insure the absence of such processes, was the exclusion of the bacteria. The next question was, Whence did the microbes come? They are contained in the atmosphere. Either the air must be completely excluded from a wound or be made aseptic. That the air really was the carrier of these pathogenic bacteria has not only long since been proven by experimental research; but surgical experience has also clearly demonstrated the correctness of this view. It is a well-known fact if we cut the integument and tendon with a knife, that the chances of complete recovery are not very good, besides the risk, that intense suppuration accompanies the cure. But if a tendon is divided subcutaneously, so that air cannot enter, the wound heals kindly, with great rapidity, and without the formation of pus. Formerly, the use of a trocar in thoracentesis for pleuritic effusion generally changed at once the serous extravasation into empyema; since the introduction of the aspirator needle this occurrence is not quite so frequent. Further, encephalitis following an injury to the skull, even if a splinter of the diploe pierce the tissue of the brain, is not apt to end in abscess, but if there is a breach of continuity in the skin and bony covering of the skull, so that the air has free admittance to the inflamed focus, an abscess is almost sure to follow.

These and other undeniable proofs demonstrated beyond a doubt the fact of the air being the carrier of the pathogenic bacteria. The air had, therefore, to be excluded from a wound. But while this might, perhaps, be done after an operation is over, the difficulty was to prevent admittance of the air while the operation is in progress. That could not be achieved; the next best thing, therefore, had to be done, namely, to make the air aseptic. And to insure the complete exclusion of all bacteria, everything coming in contact with the wound had also to be disinfected, as, for instance, the hands, instruments, sponges, needles, thread, ligatures, bandage, and so on. In this manner, Lister reasoned and at once commenced his method of procedure, which has made his name immortal, and the prognosis of many a case more favorable than it would otherwise have been.

To make the details clearer, let us follow Prof. Lister in his performance of an amputation. By the aid of an atomizer, containing a six or eight per cent. carbolic acid solution, the air of the room in which the operation is to be performed is kept aseptic. This spray is kept going during the whole time occupied, namely, until the wound has been securely closed by the proper bandage. Then the instruments, sponges, and needles are brought in, all lying in a four per cent. solution of carbolic acid. Then the skin all around the part where the operation is to be performed is made completely aseptic by a ten per cent. carbolic acid solution.

With his disinfected hands, the operator now grasps the knife, takes it out of the aseptic fluid and while the carbolic acid spray passes over the parts, he makes the first incision. When the soft parts have been divided—the spray continuing to play over the wound—the saw is taken out of the aseptic fluid, and the bone, with the periosteum turned back, severed. By the aid of a thoroughly-disinfected tenaculum or forceps each artery is then grasped and a catgut ligature, which up to that time had also been kept in the disinfecting fluid, is applied to the vessel. When finally, each artery has been secured in the same manner; and while the spray still passes over the wound, the flaps are coaptated as perfectly as possible, and after that the sutures applied, disinfected needles and aseptic catgut serving for this purpose. To prevent an accumulation of discharges of the wound, and through it a separation of the well-coaptated flaps, a thoroughly-disinfected drainage-tube is inserted between the flaps at the lowest depending point to allow a free exit to any discharge. Then the parts are cleansed by the aid of aseptic sponges and a mild carbolic acid solution. Over the whole is applied the protective, generally a pliable piece of aseptic caoutchouc, and then a gauze bandage saturated with an eight per cent. carbolic acid solution, and the stump encircled by it, taking care not to compress the drainage-tube. A common disinfected bandage surrounds the whole.

Though there are sometimes more details followed in the application of Lister's dressing, the one described is that now generally adopted. But no matter what kind of bandage and how applied, the following principles, which are so masterly

explained in Nancrede's papers* must be observed.

First there must be no admittance of septic air to the wound, while the operation is progressing. This is prevented by the spray; but as the spray has been used previous to the operation, and as the skin near to the seat of operation had been disinfected, the spray need not touch the wound, as it otherwise would act as an irritant. For the same reason, the protective is applied to prevent direct contact of the acid with the healthy, fresh wound.

The next important principle is the perfect coaptation, but the stitches must cause no tension, and there must be room for the discharges to escape; for as Lister himself says, one single tense stitch may cause suppuration, though no malignant pus.

The drainage must be perfect, for the only agent likely to disturb the position of the flaps is an accumulation of the secretions. The fluid pouring out from a fresh wound is very prone to putrefy, and it should have, therefore, free egress.

Perfect disinfection is of paramount importance, for what good would all other precautions do if we do not exclude septic material? But remember, for this end the contact of the disinfectant with the wound is not needed, but rather harmful. If the operation is proceeded with as described, no septic substance can have touched the fresh wound-surfaces. After their perfect coaptation, therefore, it is only necessary to surround it with substances which prevent the passage of bacteria through them. This is done by the carbolized gauze and bandages, and the protective caoutchouc simply prevents the contact of the carbolic acid with the wound.

Finally, promotion of granulation is the last indication. By performing the other details, the parts have only to be kept at complete rest, and granulations will spring up. They do so from 48 to 72 hours after, and Von Brun follows Lister's method only thus far. As soon as granulations have well formed, he removes the bandages and treats the wound by the so-called open method. It is well known that granulation prevents the absorption of septic matter; the danger of this for any wound ceases with the appearance of granulations.

*Chas. B. Nancrede. An Analysis of the Principles upon which Depend the Modern Methods of Treating Wounds. Reprint from Archives of Medicine, June, 1881. New York, G. P. Putman's Sons; and idem, Some of the Facts of Listerism, ibidem, August, 1882.

Von Brun has reported some very favorable results from his method, but not so favorable as Lister and Volkmann, the latter following strictly Lister's method. Lister allows the bandage to stay untouched as long as the odor from the wound is sweet, or no morbid symptom, as chills and increase of temperature, indicate the entrance of septic material or the accumulation of pus in the wound. If no untoward symptoms occur, the dressing is permitted to remain until the healing of the wound, and Lister is of the opinion that this method can always be followed, and the same result will be obtained if none of the important principles of his dressing were omitted; or, in other words, if no loop-hole was left open for the entrance of septic matter, if coaptation was perfect, drainage unimpeded, and no irritant was left in the wound.

To show you some of the results of perfect aseptic surgery, let me give you some figures of Volkmann's clinic.* His wards were in such an unsanitary condition that he was at the point of demanding their closure. In the winter of 1872 and '74 he tried to save 16 comparatively simple cases of compound fracture, and 12 died rapidly of pyæmia. From 1873 to 1877 he tried Listerism in 75 complicated fractures, 73 of whom recovered.

Mr. J. Wood, of England, says: "A few years ago I believed that I had never seen a patient recover after the opening of a lumbar or psoas abscess with a free incision. I could not remember one who had not died before the opened abscess healed. Of late years I have known such abscesses opened with complete impunity under antiseptic treatment, and it seems there is nothing but this treatment to account for the difference of results."

Bruns, Berdeleleen, and Billroth performed 377 amputations by the old method, with a mortality of 29.18 per cent., while of 321 amputations performed by Busch, Schede, Socin, and Volkmann by the aseptic method, only 4.4 per cent. died.

Mr. Lister has frequently opened joints affected with hydrarthosis impending suppuration, joint abscesses, etc., in all, 109 cases, with but three deaths, all from tubercular meningitis. Volkmann gives thirty-one wounds of joints and two incisions into joints, thirty-three in all, of knee, wrist, elbow, and foot, with no death, and twenty-one compound fractures entering joints treated aseptically, with no death.

It would occupy too much time to augment

*Nancrede, ibidem.

these statistics. Those who wish more information regarding them, I would refer to the excellent treatise of Nancrede, above mentioned.

The results obtained by the aseptic method are such as to surprise every surgeon. When the opportunity is thus given to us to protect almost certainly the patient against pyæmia and septicæmia, it is my opinion that we are willfully negligent by not employing the only procedure promising success.

One great surgeon after another adopts Listerism, and whoever has once tried the method is sure to continue it. Once accustomed to it, it becomes easy of execution, and in consequence of the almost utter want of local after-treatment greatly facilitates the labors of the surgeon.

Let me hope, fellow-members of the Schuylkill County Medical Society, that I have succeeded in contributing my mite to make aseptic surgery popular with you. For your own interest, and still more for that of suffering humanity, let me pray you to adopt a method which, being based upon scientific principles and well-established truths, makes out of every wound, no matter of what part of the body, a subcutaneous one. By its aid we will drive such diseases as hospital gangrene, erysipelas, pyæmia, and septicæmia forever from the wards of our hospitals, and we will be able to guarantee to every patient a freedom from those special dangers which were the cause of the high mortality so often observed in these institutions.

Communications.

LACERATION OF THE RECTUM, BLADDER, AND PERITONEUM, BY A FOREIGN BODY THROUGH THE ANUS.

BY TOM. M. THROCKMORTON, M. D.,

Of Derby, Iowa.

Every surgeon has experienced grave results following the slightest injury, also he has observed perfect recovery from what appeared a serious if not fatal injury. For instance, a man is thrown from a horse, falling upon his head: he gets up immediately, feels sick at his stomach, vomits, and in a few moments feels all right; rides home, goes about his usual vocation, experiencing nothing unusual. In a few days—perhaps a week—after over-eating or exertion, he takes a severe headache, etc., convulsions, and dies. Again, a man is thrown out of his wagon, the wheel passing over his head, fracturing his skull and frightfully mangling his body: he recovers. I wish to give the notes of a case that came under my observation where it did not look possible that the man could survive—the character of the injury, the kind of instrument, and way the force was applied, the parts and organs complicated, all indicated an unfavorable prognosis.

August 9, 1884. Jas. Kelley, æt. 22, single, Irish descent, while engaged in running a threshing machine, jumped off the separator on to a manure or dung-fork which was sticking into the ground, the handle passing into the anus and up into the abdominal cavity fourteen to sixteen inches, as estimated by the bystanders, who are intelligent men, especially the gentleman who pulled the fork out, who is a man of *close* observation and marked intelligence—his estimate (by measuring) being that the handle *passed fully fifteen inches* up the bowel; he said "the handle showed the depth as plainly as if he had tried to measure the depth of water in a rain-barrel," the pants being woolen, without lining and *well* worn. The handle was 51 inches long, 4½ inches in circumference around the top, which was smooth and rounding, middle 3⅜ inches.

On my arrival found patient in the barn lying on a pallet of straw, countenance blanched, and of a ghastly pallor, suffering intense griping, colicky pains, retching, restless, thirsty, feeble pulse, extremities cold, had passed large quantity of blood per rectum. Gave morphia, brandy, and quinine. Made a bed in a spring wagon, and took him to his home about 1½ miles distant.

A digital examination per rectum disclosed on the anterior part of the gut a longitudinal rent or laceration about two inches in length, and near three inches above the verge of the anus.

My friend, Dr. C. Fitch, of Chariton, having over thirty-five years' experience in surgery, was called in consultation; and upon his arrival, about seven or eight hours after the injury, the patient had reacted and was resting quite comfortably.

Passed catheter and drew about eight or ten ounces of turbid or bloody urine. Patient was then placed in lithotomy position, after being anæsthetized by my brother, Dr. C. M. Throckmorton. We had a variety of anal specula and dilators; these failing, we contemplated the division of the sphincter ani. However, Dr. Fitch, with Sims' duck-bill vaginal speculum and volsella forceps, succeeded in bringing down the bowel sufficiently, and I closed the rent with two interrupted sutures of silk. Bowels syringed out, and patient put to

bed. Then remembering the words which I heard fall from the lips of our lamented, venerable, and learned Prof. Gross: "Gentlemen, *in peritonitis, put the bowels in a splint, and do it with opium.*" I gave morphia sulph. in gr. ss. to gr. j. doses to relieve pain, tranquillize the system, and to prevent the peristaltic action of the bowels; relaxing the abdominal muscles by raising the shoulders and placing pillows behind the knees. The entire abdomen was covered with cloths wrung out of hot water, medicated with plumbi acetas and tr. opii, and these again covered with dry ones, changing every fifteen to twenty minutes. All solid articles of food carefully avoided—beef essence, animal broths, slops, milk, etc., being the entire diet.

August 10 (second day), 7 a. m. Temperature, 101½° (in axilla); pulse, 104. Vomited about one pint of bilious or greenish matter. Passed catheter and drew only a few drops of bloody urine. 7 p. m., pulse, 108; temperature, 102°. Bloody fluid having a decidedly urinous odor passing from anus every time patient moved or turned. Inserted soft, flexible catheter, and retained it in position.

August 11 (third day), 9 a. m. Pulse 96, temperature 102⅛°. A good night's rest, took nourishment, milk, lime-water, beef tea, etc. Urine more clear, flowing from catheter, also some per rectum. Eyes jaundiced. Tongue coated with brownish fur. Bowels tympanitic and tender on pressure. Changed to dry bed, withdrew catheter, cleaned and returned it. Washed nates and genitals with carbolized water, keeping up the hot applications and opiates. 9 p. m., temperature 102¾°, pulse, 100.

August 12 (fourth day) 10 a. m. Pulse 90, temperature 100¾°. Urine more clear, and not so free from rectum. Irritation of urethra, but not so much tenderness over bowels. 8 p. m., pulse 98, temperature 102°.

August 13 (fifth day), 10 a. m. Pulse 88, temperature 99½°. Rested well, sweat, slight headache. Some desire to have bowels moved. Gave opium instead of morphia. Gas passing through catheter having a decided fæcal odor. 3. p. m., pulse 100, temperature 101¾°.

August 14 (sixth day). Flighty through night. Not so much urine passing per rectum. Catheter left out on account of urethritis. Temperature 98°, pulse 78.

August 15 (seventh day) 10 a. m. Temperature 100¼°, pulse 75.

August 16 (eighth day), 7 a. m. Temperature 98⅗°, pulse 68; 8 p. m., temperature 100⅖°, pulse 76.

This carries us over the first week with this interesting case, and to give every detail would take too much space and time; suffice it to say, on August 20 (twelfth day), on withdrawing the catheter the eyelet was filled with fæcal matter, and upon examination digitally the sutures had come away, the rent had closed so as not to admit the index finger, and feeling not unlike the os uteri.

August 21 (thirteenth day). Pulse 80, temperature 101⅖°. Bowels moved for the first time, assisted with enema and scoop, patient having a desire to strain and bear down, passing per urethra considerable fæcal matter in form of small lumps—grains of green corn—after which I washed out the bladder with tepid carbolized water by means of inserting a small pipe of a Mattson syringe into a soft catheter. Did this frequently during the entire treatment, and sometimes the water would flow back, looking like an alvine discharge. Also kept the bowels well cleansed.

August 27 (nineteenth day). Bowels moved again—the second time since injury—several large stools. Passed fæces per urethra as before. From this time on kept the bowels in a soluble condition, sustaining patient on liquid diet, and such articles as would produce as little fœcal matter as possible. At the end of nine weeks patient passed some urine per rectum, compelling him to take down his pants to urinate; but by voiding his urine several times in the twenty-four hours, keeping his bladder empty, *a perfect cure was accomplished*, the tract healing up by granulation.

Were I to treat the case again, I would do just as I did, with the exception that I would try to put in more sutures. However, we were not certain as to the extent of injury, and thought it proper to leave ample room for drainage; nor were we certain just what part, or to what extent the bladder was injured, as the patient had not voided his urine for several hours prior to the injury, and falling forward at that time, the handle may have ruptured the viscus by pressing it against the symphysis pubis, or what is more probable, it entered the bladder below the recto-vesical fold and passed out at the summit—for I do not think the bladder could have risen high enough to have permitted the impalement of the body to the depth of fifteen inches without laceration.

During the treatment of this case I was at times hopeful; again, it appeared my man could not recover; but in the language of my friend, Dr. O. H. Allis, of Philadelphia, "Do all you can

—then leave the rest with an all-wise Providence." In so doing, I felt *I had done but little* "in doing all I could," and that an all-wise One *did* do the rest.

ON THE USE OF ANÆSTHETICS IN MIDWIFERY.*

BY J. B. CORY, M. D.,
Of Denver, Colorado.

Natural labor is a physiological process. The most successful obstetricians are they who do not interfere with the natural forces, unless they are hindered or obstructed by an abnormal condition of the nervous or circulatory systems, a malposition of the fœtus, abnormal growths, or deformities.

To watch and wait, is sometimes greater evidence of skill than a brilliant operation.

"Meddlesome midwifery is bad," is a saying we have often heard, but, perhaps, have not sufficiently considered.

Frequent examinations during the first stage of labor, pulling and stretching the os uteri to hasten the dilatation, premature rupture of the membranes, the use of ergot before dilatation is fully accomplished to increase the force of the uterine contractions, frequent injection of antiseptic solutions to destroy imaginary germs, the use of the forceps to save time, and the use of anæsthetics to such an extent as to retard labor, are some of the evils of the lying-in room that we ought to guard against.

I would not be understood as detracting in the least from the important duties of the accoucheur. With just as much reason might a ship start upon a voyage without a helmsman at the wheel, as may a woman enter upon the labor of childbirth without a trained and experienced assistant. As the helmsman may set his ship upon its course and rest at ease during the calm or when the wind is favorable and constant, so may the accoucheur sit idly by as labor progresses easily and safely. But as the helmsman must be ever vigilant, with his eye upon the compass, or scanning the horizon to anticipate the coming storm, so must the accoucheur be ever watchful for the least deviation from the natural course of labor, and ready at a moment's notice to give assistance as it may be required. It is his business to "look out for breakers" that indicate approaching danger, and with skill and judgment guide the patient through the trying ordeal.

Among the various means for accomplishing this result, is the use of anæsthetics. And one of the important things for him to know, is when and how to use them. Of the anæsthetics that may be used, I give the preference to chloroform, pure and unadulterated, because it acts more rapidly, and with less excitement than the others. The only objection that can be urged against it is its want of safety. But the experience of forty years has demonstrated that when properly used in a case of labor, it is devoid of danger—for the reason that it is never necessary to produce complete unconsciousness, except in cases requiring operative procedures, and because the efforts of nature in a case of labor tend to fill and make turgid the vessels of the brain, and thus counteract the dangerous action of chloroform.

I am not an advocate of the indiscriminate use of anæsthetics in midwifery. There are many cases in which, to say the least, they are not required, and others in which their use would be detrimental.

Many women will suffer but little during the first stage of labor; will perhaps walk about and chat and laugh in the interval between the pains, and in the second stage are cheerful and hopeful in anticipation of soon holding in their arms the little stranger for which they have been so long waiting. In cases that pursue so favorable a course as this, why should we blunt the senses and obtund the intellect, and take the risk of possible accident and censure, by giving chloroform? But we sometimes, indeed quite frequently, meet with cases that are not so free from embarrassing complications. The os uteri may be rigid, and not disposed to dilate freely and easily. The constantly recurring pains, which to the patient seem to be doing no good, bring about a condition of hyperæsthesia and nervous irritability that harasses the patient beyond endurance.

In such cases the anæsthetic is invaluable, and should always be used. A few inhalations from a handkerchief upon which a few drops of chloroform have been placed acts like magic. Pain is allayed, nervousness subdued, hope restored, the rigid os relaxed, and labor progresses easily and satisfactorily.

A similar condition sometimes obtains in the second stage. Not many days ago I was called to a lady who had been in labor with her second child for eight or ten hours. The messenger requested me to take my instruments, as her first child had been delivered with forceps, and was stillborn; and from the condition she was in, he had no doubt but they would have to be used

* Read before the Denver Medical Association, February 10, 1885.

again. On my arrival, I found her very much excited, throwing herself from one side of the bed to the other, and screaming with pain. She begged me to use the instruments and relieve her immediately, or she would surely die. She was sure the child could not be born without them, and was willing and anxious to sacrifice its life to end her suffering.

On examination, which, owing to the sensitiveness of the parts, was very superficial, I found the os fully dilated, and the head beginning to press upon the perineum, the membranes intact. I ruptured the membranes, and immediately began the administration of chloroform. In a short time she became quite tranquil, and without becoming unconscious was able to endure the pain without complaint, and was soon made happy by taking in her arms the innocent cause of all her suffering.

In nearly all cases I like to give a few inhalations at the end of the second stage, as the head is pressing upon and passing the vulva, especially in primiparæ, and when the perineum is tense and resisting. I think it lessens the danger of rupture of that organ, and patients are usually very grateful for the relief it gives.

As a matter of course we should give the anæsthetic before the operation of turning, the application of the forceps, or other operation that may become necessary to complete the labor. In such cases it is best to produce full anæsthesia, and the anæsthetic should be given by a competent assistant, so that the operator may give his individual attention to the work before him. As soon as the feet are brought down, or the forceps have been applied and locked, the patient should be allowed to come partially from under its influence, so as to assist, by bearing down, in the expulsion of the child. In other cases I think it best to stop short of complete unconsciousness. My favorite method of giving it is to take a handkerchief, fold it so as to be about four inches square, spread it in the open palm and pour upon it a few drops, not more than a drachm, of chloroform, and close the hand tightly over it; then watch for a pain, or in cases of great excitement do not wait, but hold it lightly to the mouth and nostrils, opening the hand enough to liberate the vapor of the anæsthetic in such a way that it will be pretty freely mixed with the atmosphere before being inhaled. As soon as the pain is gone, or the excitement subdued, withdraw the hand and clasp the handkerchief till the approach of another. More chloroform can be added from time to time as it evaporates; but if the handkerchief is tightly grasped during the intervals, it can be kept for some time. The patient should lie on her side.

Hospital Reports.

A CLINICAL LECTURE.

BY WM. H. WATHEN, M. D.

(*Continued from page* 330.)

I will spend the remainder of this hour, gentlemen, in discussing sterility in a general way.

Sterility is from the Greek στερεσο—barren—implying an incapacity for conception, and has as synonyms, infecundity, barrenness, and infertility. It is mentioned in the earliest medical literature, and biblical writers often refer to it as a reproach to woman. Since married life is seldom happy without children, frequently causing the husband or wife to become nervous, fretful, and morose, it is the duty of every physician to study this subject thoroughly. Married women who remain sterile will not believe they are perfectly formed. Not only does the happiness of married life depend upon having children, but also the perpetuation of names and families, the descent of property, and the permanence of dynasties and governments. You will probably be surprised to know that in Great Britain alone there are 500,000 married women sterile. This condition may be absolute or relative, congenital or acquired. In absolute sterility there is no impregnation of the ovule; or if the ovule be impregnated, fixation to the uterine mucous membrane is prevented, and there is no conception, the ovule being destroyed in the tubes or the uterus. In a form of sterility called "sterility not absolute," conception occurs, but abortion follows before the child is viable. In relative or acquired sterility, the woman has had one or more living children, but in number not according to the duration of married life. One child sterility exists in one out of thirteen fertile marriages. There is a high degree of both absolute and relative sterility in heiresses. In the British peerage there is one sterile woman in six and a half marriages, while there is but one sterile woman in ten in the agricultural and seafaring people. In 100 marriages in the British peerage 414 children were born, while in 100 marriages not heiresses there were born 624 children.

The average time from marriage to the birth of the first child is 17 months, and the average time between the birth of children 19 months, and women upon an average bear children from 25 to 38 years of age—less than 15 years.

As one in 13 fertile women bear their first child after having been married 3 years, no woman should be presumed to be sterile until the fourth year of married life.

In order to thoroughly grasp the subject of sterility, it is necessary to keep constantly before the mind a clear idea of the physiology of conception. Several factors are concerned in the process of conception, and these should operate in harmony. The woman must produce healthy

ovules, and the man must secrete healthy spermatozoa. In each there must exist no conditions that destroy the vitality of the ovules or the spermatozoa before they come in contact, and this contact must take place under the proper conditions to produce impregnation. Then there must be no condition which prevents the fastening of the impregnated ovule within the uterus. Thus, you see, conception depends upon the combined forces or matter of two individuals, male and female.

The popular, as well as a large share of professional opinion, that sterility is nearly always due to some defect in the woman, is by no means correct.

Gross's statistics show that sterility is found in man on an average of one case in six. Statistics show that in 83 cases of bilateral epididymitis, only 8 afterward had healthy spermatozoa in the semen, due probably to obstruction of the vasa deferentia. They also show that 90 per cent. of sterile women are married to men who have had gonorrhœa before or since marriage. Spermatozoa may be secreted, yet in copulation not ejaculated on account of some congenital or acquired defect, or their vitality may be destroyed by the secretions of latent gonorrhœa. When secreted and evacuated, they may be prevented from entering the uterus by any congenital or acquired defect that interferes with sexual connection, such as imperforate hymen, atresia vaginæ, etc., or from contraction of the external or internal os, flexions, or conoid cervix. Or their vitality may be destroyed by secretions from unhealthy conditions of the mucous membrane lining the uterus, cervical canal, or vagina. These secretions may take place from glandular cervical endometritis, from areolar hyperplasia, or from latent gonorrhœa. Tumors connected with the uterus, or within the parenchyma of the uterus, or any disease of the mucous membrane or walls of the uterus, may not only prevent the entrance of semen into the womb, but also prevent fixation or conception of the impregnated ovula. Healthy ovules may not be produced on account of enfeebled health, from sudden profound shock to the nervous system, causing ovarian incapacity, or from any disease in or about the ovaries, such as chronic ovaritis, cystic, sarcomatous, cancerous, or inflammatory degeneration, or from peritonitis and cellulitis. Of course there are no ovules in the absence of the ovaries. When they are secreted in a healthy condition, their entrance into the uterus may be prevented by displacements, detachments, or absence of the fallopian tubes, or by any condition that abstructs, contracts, or obliterates their cavity.

The theory of mechanical obstruction has been almost universally taught in this country and in many parts of Europe: but recently the theory that sterility is due to local uterine disease has obtained a strong foothold in some parts of Germany, and especially in and about St. Petersburg. You may infer from my remarks that I am not wedded to any one theory of sterility, but believe that it may result from mechanical obstruction, from local uterine disease of the female generative organs, or from constitutional diseases, or finally, that it is often dependent upon some abnormal condition in the husband. Some women, while potentially fertile, are actually sterile, or may have relative sterility. This is seen in women who marry successively two or more men and have children by only one of them, or where a man marries two or more childless widows and has children by each of them. This may be styled sterility from incompatibility. Sedentary habits, confinement, changes in climate, obesity, and inter breeding, are causes of absolute and relative sterility. That spasmodic dysmenorrhœa is a cause of sterility is shown by the fact that in 332 women absolutely sterile, 159 suffered from this trouble. Most fertile women have pleasure in sexual connection, and may also have desire; but women may conceive who have neither desire nor pleasure, while others who have desire and intense pleasure remain sterile. In the absence of some positive condition in the woman that will prevent conception, we should not determine that she is sterile until we examine the semen of the husband to see if it contains living and healthy spermatozoa. While a woman with syphilis may have absolute sterility, sterility not absolute, or relative sterility, we also know that sterility not absolute and relative sterility are often the result of syphilis in the husband where the wife is not infected.

In the treatment of sterility, first try to find the cause, and then to remove it. Unfortunately, we see many cases that we cannot benefit; but others can be cured. Correct abnormal constitutional conditions, and attend especially to the secretions and the excretions. If the woman is anæmic, or her general health degraded, give nourishing and easily digested diet, tonics, constructives, and alteratives; if she has syphilis, treat that; if she suffers from obesity, reduce her flesh; if she is constipated and has indigestion, give her a gentle laxative containing podophyllin to stimulate the portal circulation, belladonna to act upon the mucous membrane, nux vomica as a tonic to the intestinal muscular fibres, and aloes as a stimulant and tonic to the pelvic vessels to remove passive congestion. Cure any disease or condition that prevents complete or perfect sexual connection, and any disease that causes a secretion or discharge poisonous to the spermatozoa. If the ovules are prevented from entering into the uterus, or are not developed on account of inflammation of the ovaries or of the cellular or peritoneal tissues of the pelvis, use copious vaginal injections of hot water, and apply counter irritation by means of croton oil, cantharides, or iodine over the inguinal regions, to promote absorption of inflammatory products. But if there is contraction of any part of the cervical canal, or obstruction caused by flexure in the cervix, or an elongated conoid cervix which prevents the entrance of semen into the uterus, then I wish to enter my earnest protest against the treatment of Sims, Thomas, Emmett, and others, who advise the use of tents, bilateral incisions, splitting up a lip of the cervix, or amputation of the cervix. Such treatment seldom does good, and often results in evil. Much more scientific and successful results will follow rapid dilatation of the cervical canal to the extent of three-fourths of an inch to an inch and a quarter. Occasionally it may be necessary to make superficial quadrilateral incisions around the external os. The rapid dilata-

tion will generally remove the obstruction from stenosis or flexure, and will tend to straighten and shorten the cervix and to alter its shape.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, Friday, January 2, 1885, the President, Richard A. Cleemann, M. D., in the chair.

Double Uterus and Vagina.

Dr. Wm. Goodell described a case which had been sent to him on account of pain in the back, various nervous symptoms, and difficult coition. The vagina was double throughout its entire length. Entrance had apparently been effected indifferently on either side of the septum. The cervices were united like the barrel of a double-barreled gun. There was a slight divergence of the upper third of the fundus. The sound entered three inches into each cavity. The septum vaginæ was divided up to the cervix, and her physician reports great relief to the general symptoms.

Dr. C. McClelland described a similar case. Pregnancy had progressed to the third month when the case came under his observation. The vaginal septum was complete. The external contour of the cervix was normal, but a thin septum extending from the os to the fundus divided the cavity into two parts. The prominence of the uterus was greater on one side of the abdomen. The sound was not passed. The vaginal septum was divided shortly before labor. A living child was delivered. About the third day after delivery, a mass, apparently of decidua, was thrown off after three or four hours of labor pains. After involution was complete, sounds were introduced into the uterine cavities, and the handles diverged one and three-fourths inches. A second conception occurred afteward on the other side of the uterus.
